In regard to power as coercive causation, John Harsanyi (1962) emphasized costs of exercising power and also the costs of compliance with the exercise of power. For instance, a lobbyist might change a legislator's vote with little cost if it just means arranging a meeting with one of the legislator's staff. On the other hand, the cost is high if the lobbyist must mobilize hundreds of persons to petition the recalcitrant legislator. From the standpoint of the legislator, a vote may be cheap, offending almost no one, or it may endanger victory in the next election. Still another causal situation occurs when A's preferences cause changes in B's preferences, causing B to act differently. This is widely known as *anticipated reactions*, in which B, perhaps to please A and to avoid A's exercise of sanctions, changes behavior in line with an anticipation of what A wants him/her to do, even though A did not explicitly state such preferences (Nagel, 1975).

An important, implicit aspect of defining power as causation is its link to empiricism. A statement of power then implies observations of instances of A changing B's behavior. It rules out defining power in terms of resources (wealth or force, etc.) used to get B to comply. One first has to observe the causal relationship; then one analyzes how power was wielded. Such resources were called by Dahl a power base, and both he and Simon (1953) stated that the power base should not be confused with power itself. In addition, Dahl stated that power-as-causation, to be an empirically useful concept, had to be used with four concomitant dimensions of power: base, amount, scope, and domain. *Base* then refers to the resources or means that A uses to cause changes in others' behavior. *Amount* refers to the idea that some instances of power refer to greater changes in behavior than others. A lobbyist exercises more power when he/she changes the legislator's vote from no to yes, for instance, than if the change is only from abstain to yes. The *domain* of an actor's power consists of those persons subject to an actor's power. The *scope* of power consists of the matters subject to the actor's power.

Dahl's major contribution to the study of political power is his insistence that domain and scope always be clearly stated in discussions of power. Or to put it in another way, an actor's power in one situation should not be immediately generalized to postulating equivalent power over other persons in other

situations. The pharmaceutical lobbyist may have power over just one or over a score of legislators regarding the regulation of generic drugs. The same lobbyist might not have equivalent power over Medicare payments for prescriptions; this lobbyist may have no power at all over any legislators in regard to civil rights or to gun control.

Scope and domain of power were key issues in the still widely remembered *community power debate* of the 1960s. Following the example set by Dahl in *Who Governs?* (1961), political scientists studied political power in localities by conducting case studies of public policy-making and charting which persons changed the course of events. Such studies normally found that the domain and scope of power was fragmented; different persons had power in different areas of policy. Other social scientists – tending to be sociologists – followed a different conception of power, conceiving power to be possession of wealth or high social status. Such observers usually described inequalities of wealth and status and stated this finding as a finding of power in a community. Political scientists, on the other hand, for the most part did not consider wealth and status to be power itself, but instead to be resources that could be used to win political power, if such wealthy or high-status persons intended to do so. But such intentions are an empirical question, in this view, and must be observed in case studies.

This famous (or notorious) controversy extended for at least a decade, was expressed in scores of books and hundreds of journal articles, before the frustrated debate participants, unable to persuade one another, for the most part went on to study questions other than community power (Polsby, 1980).

Proponents of power-as-resource generally overlook a strong criticism of the power-as-causation model. Social causation is ordinarily very complex; case studies are not easy to do; power as causation thus is ordinarily complex, requiring a great of effort to study. Such writers as James March (1955), Herbert Simon (1957), John Harsanyi (1962), and William Riker (1964) left us with elaborate statistical models for studying power, models which require costly and difficult data collection. Jack Nagel (1975) wrote a concluding work in this line of analysis, in which power-as-causation was stated as path analysis, a form of statistics.

Power and Policy-Making

William Riker (1964) and James March (1966) were both noted for asking the question in respect to political analysis: "what is the power of power?" Political scientists answered this question, not by flocking to do more studies of the holders of wealth and status, but by stating models of power structure applied to political systems, both national and local. Robert Dahl (1961) had pressed forward the definition of power-as-causation in the course of his empirical refutation of the power elite model of Floyd Hunter (1953) as applied to the city of Atlanta and the later statement of the elite model by Wright Mills (1956). Such writers were among those who described power by describing characteristics and activities of an elite group, whose actual exercise of power usually went undemonstrated. Scholars such as Dahl became known as describing a *pluralist model of power*, finding power to be fragmented among various scopes and domains, as opposed to the concentration of power within a single elite.

Scholars such as Murray Edelman (1964), Grant McConnell (1966), and Theodore Lowi (1979), on the other hand, agreed that political power in America is fragmented, but argued that stable, unrepresentative elites often control policy within specific scopes of power – such as setting grazing fees on federal lands, developing nuclear power plants, setting airline and interstate trucking schedules and fees before they were deregulated. Such analyses, which flourished briefly, also were based on case studies of policy-making and constitute a school which might be termed *multiple-elitist*, finding not a single power elite but hundreds of elites, each specific to a particular scope of action and not subject to control by elected officials. But multiple elitism in turn faced a revisionist interpretation, *neopluralism*, as found in studies by James Q. Wilson (1980) and Jack Walker (1991), for instance, who found that while power within specific scopes of policy was normally unequal, it was nevertheless shared by so many organized interest groups, politicians, and government agencies that even within narrowly defined policy scopes, stable and controlling elites are seldom found (McFarland, 2004).

The power-as-causation model was developed during 1953–75, and the examples cited in this literature were almost always power among individual persons. But given the great difficulties in gathering such data, political scientists seldom conducted such studies, and instead, the analysis of political power flourished with the development of models of policy-making just cited. Such scholars saw no need to worry about possible criticisms of ignoring the power bases of wealth and status, and continued to conduct case studies of policy-making, following Dahl's example, even as many argued with Dahl's pluralist model. Such case studies were not conducted according to the canons of path analysis or other forms of statistics; instead such researchers used historical materials, interviews, and current documents to ascertain which groups, leaders, and government agencies caused changes in the course of public policy (Baumgartner et al., 2009). Relatively simple empirical methods, assuming power-as-causation, have been enough to generate interesting models of power structure, but perhaps more complex methods will be needed to resolve differences among various schools of political power analysis.

The study of political power has developed satisfactorily since Herbert Simon's seminal article in 1953, but a great theoretical difficulty remains – the problem of *hegemony*. Hegemonic writers stress the great importance of the power to determine which issues are on the political agenda of a political system (Lukes, 1974). Community power theorists Peter Bachrach and Morton Baratz (1962) argued that there are 'two faces of power,' the first face being power over overt activity on issues already considered in the system as studied by Dahl. Still to this face must be added a second face: power over the formulation of political issues yet to be considered by the political system. In arguing for the understanding of hegemony, the Marxist Antonio Gramsci argued (1971) that capitalism maintained its political power through the socialization of persons into supportive values and norms as much as through the machinations of bourgeois government. Social values shape the preferences of the actors in their search for political power, but how can the scholar make empirical

statements about one set of values displacing perhaps hundreds of conceivable alternative value systems? This seems to presuppose a comprehensive theory of social relations.

Hegemony can be distinguished from the power of *anticipated reactions*, power exercised when B anticipates A's intentions, and acts in accordance with them, perhaps fearing the costs of A's overt coercion. Republican members of Congress may have considered blocking appropriations for a government department, but anticipating President Obama's effective reactions, they think better of the idea and do little but discuss the matter. But since the matter received some discussion, the theorist of political power may make an empirical observation.

During the 1980s mainstream political scientists normally accepted the three-point progression in the understanding of political power: (1) power as causation in which person A gets person B to do something A intended, but B initially resisted, that is causing intended changes in another's behavior; (2) adding to the foregoing or the 'first face of power,' the 'second face of power,' control over the appearance of those issues over which persons contended to realize their intentions; and (3) control over the development of individual intentions, even before such intentions become expressed as political issues. Acceptance of the power-as-causation model accompanied an understanding that others, often critics of the social status quo, preferred to refer to power in terms of resources (especially wealth), resources to gain one's way in the exercise of political power.

After accepting this threefold understanding, many political scientists accepted Charles E. Lindblom's structural model of power, which accepted power-as-causation but proclaimed the necessity of understanding the social structures which shaped the issues getting to the political agenda and the political socialization processes that shaped the goals behind such issue definition. Accordingly, in regard to political power in the United States, Lindblom stated 'the privileged position of business' in having the power to shape intentions through advertising, and the power to affect the placement of issues on the political agenda, particularly through the capacity to move jobs from one place to another, or to refuse to invest unless receiving favorable treatment in systems of taxation and government regulation. Lindblom's structural regime theory became a widely accepted, although infrequently explicitly stated assumption, for those conducting empirical studies of political power exhibited in elections or lobbying (Lindblom, 1977).

Such concerns were brought together in the landmark study of lobbying and political power in issues considered by the American national congress. Accepting the power-as-causation model, five political scientists and their research assistants conducted 315 interviews and manuscript background research for 98 case studies to develop narratives of who caused what to happen on 98 separate issues. The study only weakly demonstrated the power of business, because it seemed that the status quo already exhibited business power, and most political power was exhibited in vetoing those seeking to change the status quo, including businesses seeking to expand their power over political issues. From another perspective, this *Lobbying and Policy Change* study demonstrates the great effort needed to gather sufficient data to demonstrate who has power according to the power-as-causation concept. Individual researchers need be aware of this, and lacking the resources to develop many case study narratives, then be prepared to make plausible, evidence-based statements about successful exercise of political power, which might leave some element of uncertainty due to the difficulty of estimating the g complex causation involved in political interactions (Baumgartner et al., 2009).

Foucault and Power

Beginning in the 1990s, the ideas of French social theorist Michel Foucault (1926–84) provoked a great deal of discussion among American social scientists as they had done among the French somewhat earlier. Foucault's views about power differed from those in the causation, limitation by general social structure, or resource perspectives mentioned above. Foucault viewed power as manifested within normative systems controlling human behavior within specific institutional structures developed by processes of modernization. These institutional structures included prisons, factories, schools, universities, hospitals, mental hospitals, military barracks, and charity and philanthropic institutions. Systems of knowledge pertaining to each institution define and comprise it and control human behavior within the institution. Such systems include philosophies of education, professional norms such as those of medicine and law, academic disciplinary norms, criminology, social work and sociological theory, military leadership, and especially psychoanalysis and other systems of psychological theory. Foucault's views even extended to the perpetuation of norms controlling behavior by the family and by sexual interaction (Foucault, 1977).

Opposed to defining power as one agency dominating another, Foucault defined power as control through a system (although he avoided the use of such general, abstract terms). Foucault devoted years to research concerning 'discipline and punish,' the overt use of social sanctions to prevent deviant behavior and to change the behavior of miscreants back to the group norm. Yet Foucault clearly believed that almost all persons most of the time accepted the social norms of the institutional system and did their best to behave accordingly. In particular, the institutional rank and file do not differ from institutional leaders and disciplinarians in their views of right and wrong behavior. Almost everyone accepts the legitimacy of system norms and in fact participants' behavior embodies the norms (Brass, 2000).

Institutional participants are constantly observed by others in the system and additionally participants (perhaps best termed 'subjects') constantly observe themselves to identify and to correct behaviors that deviate from the system norm. Institutions have a knowledge base such as professional or academic disciplinary norms to control behavior, and examinations are given to subjects to measure proficiency in such knowledge. The institution accumulates data about each of its subjects to observe and examine how well each subject is adhering to the institutional norm. The institution is thus a self-perpetuating system. Thus the modern political world is characterized by subjects (lacking individual autonomy), not citizens.

Foucault's theory of power thus can be linked to Putnam's theory of civic engagement, probably the theoretical

perspective getting the most attention from American political scientists in the period roughly 1998–2008. Foucault's institutional systems can be characterized as inducing a high degree of cooperation, to the degree that we can neglect individual agency. Robert Putnam and Theda Skocpol among others have been concerned about the decline and frequent disappearance of voluntary associations (somewhat neglected by Foucault) as well as face-to-face interaction among neighbors. They argue that face-to-face interaction within associations promotes interpersonal trust, subsequently enhancing the capacity to cooperate, thus promoting democratic citizenship. The Putnam–Skocpol theory assumes individual agency among collapsing institutions; Foucault's theory assumes a lack of agency among self-perpetuating institutions. But both theories posit a lack of citizenship capacity among citizens, either because they lack individuality or because they as individuals cannot cooperate with other individuals. In such conditions, society obtains power elites (Putnam, 2000; Skocpol, 2004).

International Relations

The term 'power' appears in international relations research probably more often than it appears in any other scholarly field. International relations scholars, foreign ministry leaders, and military officers have been centrally preoccupied for centuries with the state of 'the balance of power.' Currently both ordinary language usage and scholarly writings about international relations generally refer to power in the sense of necessary resources for national security, particularly military and economic resources. In current language such resources are termed 'hard power,' as opposed to 'soft power,' generally the nonmaterial resources that boost a state's prestige, helping it to compete in the international system: its moral stature, such as in human rights, its export of prestigious cultural activities.

However international relations scholars have developed more technical uses for the term power. Within this field, the most common technical definition of the term power has been Robert A Dahl's basic definition (see above) with the addition of the element of intentionality: the ability of A to get B to do what A wants even though B initially resists A's intention (Barnett and Duvall, 2005: 49). This means, however, that power is a type of social causation because A changes B's behavior, but in many international situations to be studied, causation and hence power is complex, hence difficult to ascertain.

Much of international relations theory is systems oriented, meaning that the system of interaction constrains the behavior of decision-makers, so that causal definitions of power do not add much to our understanding of state behavior. It is best here to refer to system determination rather than the exercise of power by an individual agency. Yet some clear cases for the causal definition of power can be found in the relatively simple interactions within a short time frame, such as militarized disputes among two nations, or in general what can be considered to be a single foreign policy crisis between two nations. In such situations it is relatively clear that one state caused a change in behavior (policy) by a second state.

International relations literature places emphasis on a state's acquisition of resources that can be converted into power within the system (i.e., achieving intentions against initial opposition). This sometimes implies manifesting resources (military, economic) that deter others from resisting or deter others from achieving their intentions, opposed by the first power. In the study of domestic politics, such deterrence is referred to as 'anticipated reactions,' meaning actor B anticipates that actor A will oppose some action by B, and that B will subsequently be the loser as having less power resources than A, so that B never attempts the action at all. An observer can say that A deterred the action by B through B's anticipated reactions. As a parallel international relations scholars frequently refer to 'deterrence' between or among states in regard to possible state actions. The well-known and common use of deterrence refers to Cold War interactions between the U.S. and the U.S.S.R., as each deterred the other from the use of nuclear weapons to gain foreign policy goals. This is based on the idea of power as causation, in that we might say that the U.S. deterred or caused changes in the behavior of the U.S.S.R., dreading the use of nuclear weapons, while the reverse was also the case. However, anticipated reactions and deterrence theory in international relations is usually dependent upon counterfactual hypotheses; the observation is that something did not occur that otherwise would have occurred due to strategic restraint on the part of a state or actor. Dependency on counterfactuals is certainly a difficulty in the use of power as causation to analyze deterrence situations, although study of documents and interviews of participants, usually at a much later time, can provide data to understand what did not happen (Jervis, 2013).

International relations scholars have dealt with the difficulties in using power-as-causation by using 'end-run' strategies to flank the problems posed by complex causation. One such strategy is to rely on the concept of international system as the major causal factor. Another such theoretical strategy is 'regime theory,' which focuses on constraints on the behavior of international actors by interlocking behavior norms and shared framing of the meaning of international behaviors. The major example of regime theory is the category 'liberal international economic regime,' indicating a widespread belief in and practice of free trade among nations, combined with aspects of market theory such as rules for repayment of international loans made by states or by international agencies such as the International Monetary Fund and the World Bank. In using the regime theory framework, one can avoid directly causal statements about power and instead focus on describing the interpretive frames (particular simplifications of complex situations) that constitute the system of regime norms and how such interpretations of norms and beliefs are employed by state and nonstate actors (Krasner, 1983).

Michael Barnett and Raymond Duvall (2005) write that in international relations theory, it is best to state that power is fourfold. A particular study might focus on one of the four ideas of power, although in addition, scholars can frequently find links between the types. The Barnett and Duvall system is another attempt to avoid the complexities of observing power-as-causation. Their basic definition of power goes beyond gaining one's way in a specific social interaction and adds a dimension of producing social effects, beyond changing the other's course of action, that enable further control in subsequent social situations: "Power is the production, in and

through social relations, of effects on actors that shape their capacity to control their fate" (Barnett and Duvall, 2005: 45). Their first definition is 'compulsory' power, one actor compels another to change course in line with the first actor's intentions in a specific or series of specific social interactions. This is much the same as Dahl's power-as-causation. Their second definition of power is 'structural power,' meaning that social structure directly affects the power of various groups, classes, and so on, in their interaction within the social system. An application of the theory of structural power to international relations is Cold War systems theory in which a balance of deterrence shaped the behavior of the two major powers. Barnett and Duvall's third type of power is 'institutional' power, in which the intentions of actors are mediated through institutions to bring changes in social relations that enhance actors' capacity to control their own fate. For instance the State Department might influence International Monetary Fund officials to grant a loan to a friendly government in order to stabilize its position. However, the concept of institutional power is subject to difficulties in causal analysis, as, for instance, if the friendly government stays in power, this might have been the result of several interacting factors. Barnett and Duvall's fourth type of power is 'productive' power, similar to the ideas of Lindblom and Gramsci noted above, and constituting a generalization from the idea of regime theory. Productive power indicates producing social effects that are not immediate by affecting the perceptions and the language of the participants. Productive power focuses on the nature of discourse and how it affects the definitions of social identity among system participants, and its most well-known theorist is Michel Foucault.

Power in Society

Abstract

Power has been seen as an 'essentially contested' concept. Some of the major recent contours of this contestation will be addressed in this article. The argument is that power is a concept whose meaning is variable in different language games and that it is important to be clear which concepts, from which language games, one is using in inquiry.

Introduction

Power has been seen as a concept that is 'essentially contested' (Lukes, 1974/2005). By this, it is meant that its essence, its central meaning, is fundamentally contested. Lukes (1974/2005) suggests this is because the concept cannot be divorced from normative perspectives. While he sees three essentially distinct normative perspectives in what he terms the liberal, the reformist, and the radical perspectives, many of the major recent contours of contestation do not follow this set of distinctions and depart in a number of ways from Lukes' concerns. The main reason for this is the eclipse of Marxist notions, which sustained the idea of their being a 'radical' view of human choices. Each of the three dimensions took a more or less voluntarist perspective on the nature of subjectivity: for the liberal, it was a matter of choices being exercised on relatively independent issues; for the reformist, it was a matter of choices constrained by a subjective and probabilistic calculation; for the radical, it was a matter of choice being constituted by structures of cultural domination. Lukes locates the basic concept of power in the work of Weber, amongst other theorists.

Weber: Ideal Types of Rule and Power

At the core of modernism, according to Weber, lies the rationalization of various institutional arenas such as the market, technology, law, state, the growing pervasiveness of rational calculation in all spheres of life, and the disenchantment of more spiritual or superstitious forms of calculation. Disenchantment means exposure to a world in which meaningfulness is never 'given.' Instead, meanings clash, struggle against the resistance of others, and are never wholly secure. Rational action consists precisely in the capacity to respond to the uncertainties of a world without meaning. Analytically, he conceived of three main types of rule around which rational action might revolve: principles of charisma, tradition, or rational legality. Each of these three types is a source of a particular type of *Herrschaft* (authority, or in better translation, domination).

In Weber's view, rationality had only a limited number of sources. It might derive from those few individuals who choose to impose value and meaning upon the world by confronting the world as something other than resolutely, unyieldingly, absolutely, and unbreakably cast in a mold. There were precious few such people in Weber's vision, other than charismatic leaders. Charisma is often identified with historical figures regarded as ordained with exceptional grace and a sense of calling that they were able to transmit and project to others, such as Jesus. Charisma is not a purely historical category, however, but it is only the rare charismatic leader, whose personal grace, sense of calling, duty, and devotion to some ultimate ideal is unshakeable, who would be able to impose such meaning on life. Hence, charisma was one of the key bases of authority that Weber identified. Genuine charisma, typically, is thought of as something above the grubby theater of mundane political wheeling and dealing: think of celebrities such as Princess Diana, who was able to parlay her celebrity into a passionate social advocacy on behalf of the victims of landmines and in so doing, bring about substantial changes in government policies. Here, was a charismatic celebrity for the modern age – especially in her death. What gave her charisma and celebrity was a fortunate marriage that rapidly proved to be ill-starred in many ways, a constant broadcast media focus culminating in an unfortunate death, all captured in images that were broadcast widely. In the past, celebrity and charisma could become deliberately entangled because of broadcast control of the image: the cult of the personality that modern leaders like Mao, Stalin, and Hitler cultivated were deliberate attempts to use tight control of the state to fashion and stage-manage a celebrity that transcended the political sphere and which sought to invest them with charisma. In modern times, celebrity and charisma are closely related but by no means the same.

Tradition functions as another ideal type, best seen in claims to authority based on lineage or dynasty, in principles of 'blood and breeding' or exclusion from opportunities to claim authority because of the lack of such blood and breeding. The succession principles of monarchy, or inheritance rights attached to property, are prime examples of rule by tradition. Most pervasive, however, as a form of authority, was what Weber took as the quintessential modality of modern rule: rational-legal bureaucracy, where rule is conducted according to abstract principles. The dominance of what Weber referred to as the rational-legal does not overwhelm all other bases for rule and authority. However, its pervasiveness is often summed up today in a popular fear of 'economic rationalism,' referring to those situations where only a legally mandated economic calculus is applied to policy formulation (such as competition policy), without regard for other ways of accounting for the impact of such policies on the human spirit, communities, and the fabric of society.

Each principle of rule posits a particular type of authority, and it is a simple matter to construct a matrix of these relations in order to generate some idea of what power might be. Weber defined power in terms of social action: power is "the probability that one actor in a social relationship will be in a position to carry out his will despite resistance, regardless of the basis on which this probability rests" (Weber, 1978: 53). An evident example of resistance to power thus arises when there are cases of conflict between principles of rule propounded by the power yielder and those thought legitimate by the resistant subject. Here, power is seen in terms of actions situated in and resisted by opposed principles or ultimate values.

Power as a Generic Concept

While Weber's definition of power is quite generic, the concept need not be premised on the conflict of rival, ultimate values. Steven Lukes (1974/2005), for instance, in one of the most influential books on the subject, regarded Weber's definition as essentially similar to the generic definition of power contained in the work of Robert Dahl (1957). Here, power is defined as the situation that prevails when A gets B to do something that they would not otherwise do. While this sounds a methodologically sparse and modern behavioral definition it is one that reaches back into the earliest development of the modern era – to Thomas Hobbes's conception of power in a causal, mechanical world.

The Community Power Debate that formed around Dahl's (1961) work concerned the distribution of power in postwar USA. Dahl (1961) insisted that such questions could only be answered empirically, rather than through a broad ranging essaying of concepts that were then current, such as their being a 'military–industrial complex.' Additionally, he thought them better answered at the local, community level rather than at the national level. To determine the distribution of power required an operational definition for empirical investigation. For Dahl, power was indissoluble from its exercise: someone had to be seen doing something to another for us to say that power had been exerted. Unlike Weber, he was not concerned with ultimate values, but he did think it important that the exercise of power should be determined by competition over issues that people thought important. Basically, he sought to determine what the key issues were in a community and then establish the outcome of the politics surrounding these decisions, to see who gained or yielded power.

Power, Real Interests, and Hegemony

By the time that Lukes (1974; second expanded edition 2005) published his book titled *Power: A Radical View*, Dahl's approach had already been criticized for leaving out of consideration 'what does not happen' by Bachrach and Baratz (1970). Nonissues, nondecision making, the construction of agendas, and the mobilization of bias through everyday routines were introduced to show how power is accomplished through covert means, through inaction, rather than through overt exercise of causal power.

Lukes took the critique one step further. He argued that the critics had only sought to qualify Dahl's behaviorism rather than transcend it through radical critique. What was required, he argued, was a conception of how power worked not only against people's expressed and implicit preferences but also their 'real interests.' The notion of real interests came from Marxist discourse – originally designed to address situations of 'false consciousness' – where a class of people were unable to recognize that the system within which they were embedded was the source of their entrapment. Lukes followed the Italian Marxist theorist, Antonio Gramsci, in introducing a 'cultural spin' on the idea of false consciousness by using the notion of hegemony. Where people were deluded about what they wanted and what they might authentically be, because of their inability to think in concepts other than those of domination and the dominated, they suffered from hegemony. The basic idea was that they were subject to a 'ruling culture' disseminated through the media, the state, education, and other institutional arenas.

Theories of hegemony became variations upon the theme of working-class acquiescence secured through normative incorporation by dominant ideology (Abercrombie et al., 1980). The narrative was one of concealment: Marxist analysis, in theory, should have provided revelation about their conditions of existence that the repressed would act on – but this rarely seemed to happen. To cover for the inadequacy of a theory whose propositions were not confirmed by practice, the theory developed an account of why the conditions that it predicted did not occur. The explanation was couched in terms of the collective inability of the repressed to be able to see and analyze the conditions of their repression, because they lacked the critical concepts to be able to do so. The repressed, in the form of the working class, were seduced by the ideas, blandishments, and inducements offered by the dominant system of repression, capitalism. They were blinded to their fate as exploited and repressed subjects.

Not everyone was blinded, however: theorists armed with the appropriate radical theory of Marxism could see the truth of the mechanisms that, despite and even through resistance, secured and reproduced consent, even while the subjects of analysis had the nature of their real interests concealed from them. However, Western Marxism, the source of these insights, was impotent at best and at worst irrelevant, in lifting the veils of occlusion (Anderson, 1976). In late twentieth century in the West, socialism became increasingly utopian (Bauman, 1977) while, in the East, it became increasingly dystopian (Feher et al., 1983), as the collapse of 'dictatorship over needs' produced its implosion.

The Discursive Turn

The ideological arguments, with their fundamental denial of the liberal sovereign subject, receded in importance in the 1980s. One response to this situation within the Marxist camp came from Laclau and Mouffe (1985), who, instead of thinking of hegemony as a state of mind, regarded it as a set of practices. These practices were primarily discursive. Hegemony thus came to be seen not in terms of its substantive content but its form. Hegemony existed when the indefinite possibilities of

signifying elements and their relations were strategically foreclosed (Laclau and Mouffe, 1985). Again, the emphasis is on things that do not happen. Any stable set of articulations is thus hegemonic: only permanent Cultural Revolution would not be, although the implications are not spelled out.

Real interests are what radical politics and theories claim to uncover and reveal. One way of doing this, suggested Haugaard (1998), that is immune to the criticism raised previously, might be to explain to actors the way in which their structured practices feed into the reinforcement of a regime of domination contrary to interests already known to them. What may be at issue are structural and institutional relations of domination rather than real but unknown interests. Once actors reflect upon their practical consciousness, they then enjoy relative autonomy. Power thus consists not so much in the suppression of real interests but the denial of the relative autonomy required for reflection (Haugaard, 1998, p. 141).

Haugaard (1998) notes that conceptions of interests form discursively, even to the extent that one can persuade some people that they have real but unrealized interests blocked by their present conditions of existence. Such discursive realities help shape them to resist the sources of domination identified. Politics mobilize power and resistance through discursive expression of existing, past, or future conditions of existence. Thus, resistance is not endemic but depends on the practical consciousness of people and the categorical devices through which they lead their everyday lives in relation to the discursive consciousness proffered by various media of representation – parties, press, radio, television, the Internet, public intellectuals, and so on. Only in rare moments is such diversity represented or resisted in the name of some great unifying narrative or theme. Most probably, these will be those relatively rare moments where a privileged identity is posited as a historical subject: the subject people, the subject party, the subject race, the subject nation, the subject church, the subject gender, the subject sexuality, the subject ecology, and so on.

A plurality of life-worlds, with interpretative resources, and translation devices for switching between them, minimizes the chances of hegemony. People from sophisticated cultures routinely have a multiplicity of interpretative horizons available to them, as a result of exposure to different life-worlds through various media, educational experiences, travel or migration, or interpersonal relations. Of course, to the extent that these experiences are compartmentalized, one way or another, the ability to achieve critical distance from any posited identity is diminished.

The theorization of autonomy in terms of moves between interpretative horizons means that the ability of actors to transcend their social environments and structured context does not presuppose an ability to 'escape' the processes of socialization by adopting a neutral, culturally unbiased, position. Autonomy does not involve a flight into any transcendental realism of absolute truth, nor does it involve the transcending of false consciousness. Critical faculty does not imply the objectivity of truth, nor does it entail an undersocialized concept of agency whereby autonomy is gained by transcending the basis of social culture. It requires only relative reflexivity on the part of subjects. Such a conception of the relation of power and knowledge, with its emphasis on conditions of relative autonomy, turns out to be a way of reapproaching the classical questions about power and community that were at the center of Dahl's work. The difference is that, this time, the approach has been through Foucault rather than Dahl.

Foucault and Power

Foucault provides a detailed history of some power practices and techniques that have characterized modernity in a way that is nonreductive and complements Weber (Dandekker, 1991), although he understates the importance of Max Weber's (1978) argument concerning discipline. Nonetheless, there are common themes (see Szakolczai, 1998). Different emphases on power occur through the course of Foucault's work. First, there is his work on genealogy as the natural history of specific practices; second, the work on the 'care of the self,' where histories are used to critique the present, by uncovering the constituted nature of what have been taken as the here-and-now and third, the discussion of government or 'governmentality.'

In Foucault's (1979) most influential genealogical model of 'surveillance and discipline,' power is constituted in an intimate relationship with liberty. Because the exercise of power presumes a free subject, there will always be resistance. Where liberty is extremely limited, because power is stable and hierarchical, Foucault terms it domination. (The parallelism of this account with that of Weber's 1978 discussion of *Herrschaft*, is evident.) Two models of power are compared and contrasted: the repressive and the positive. For the latter, power shapes subject dispositions in a variety of structural ways, of which the Benthamite panoptical device is only one colorful metaphor. (Foucault's 1979 concern with the facilitative and productive aspects of power relates to the kind of arguments made most clearly by Parsons (1963), although it is not acknowledged as such.)

In general Foucault does not offer a critique of power. It would be impossible to do so because, to coin a phrase, power has no other: it is inescapable. Liberation from power is only a dream (or a nightmare). However, specific forms of power may and do change. The 'punitive' power of corporal excess may be contrasted with the 'positive' power of bureaucracy. However, there is no space outside of power, no knowledge that is pure truth. (In this way utopia and dystopia are avoided.) In reading Foucault, it is necessary to uncouple a sociological from a philosophical question concerning truth. The former deals with what passes for truth rather than asking what is the truth and with how truth-effects are produced, in the Foucauldian vernacular. It is the latter that concerns Foucault, rather than the former.

In Foucault's model of power relationships through government – the structuring of action through conduct – which he defines as the capacity of people to regulate their own behavior through various rationalities, his treatment of liberalism suggests that it is conditions of relative autonomy that define the nature of political community.

Community Politics after Foucault

Foucault suggests that democracy is neither an ideal with which to measure actual practice nor a method for producing

utopias. It is the messy and politically expeditious ways of making sense of politics its participants routinely use. It is this fundamental approach that Flyvbjerg (1998) takes from Foucault. He provides a deeply documented, rich narrative of one complex set of issues and processes associated with the many ways in which political communities were constructed and deconstructed in the laborious pursuit of local interests and issues surrounding a proposed traffic plan for the city of Aalborg in Denmark.

Aalborg was not unusual with respect to its power relations: These relations were sufficiently asymmetric as to verge on domination, with commercial interest overriding more civic interests. Those who were dominant in power relations were well aware of their dominance and found little need to explain themselves or their actions in rational terms compared to those relatively weaker. The authority of technical rationality was a weapon of the politically weak – those without other resources at their disposal. Hence, not surprisingly, technically rational plans were constantly undercut and attempts at securing democratic outcomes based on that technically rational basis proved weak. Neither a normative emphasis on democracy nor rationality proved sufficient to avoid domination by superior power relations. Such power defined reality and, not surprisingly, the rationality accepted depended on power rather than legality. One of the main strategies of the dominant group was to use techniques of rationalization as power: indeed, the greater the power the lesser the rationality. Thus, we might conclude that power is more ordinarily stable than conflictual and that its relations are constantly being produced and reproduced in process. Where power is stable, power relations can more characteristically be legitimated in terms of a prevailing mode of rationality.

The Language Games of Power

The idea that power is an essentially contested concept presumes that there is an essence that is contested, as suggested earlier. However, having reviewed these different ways of theorizing power, it seems increasingly difficult to hold that this is the case. Either there is a great deal of error concerning the true nature of power or there is, perhaps, no true nature. Consider this: Dahl defines power in terms of its exercise; Foucault sees it in terms of subject dispositions; Weber in terms of might and domination, while Lukes sees it in terms of hegemony. Can they all be correct? Is one right and are the others wrong? Or, as Haugaard and Ryan (2012: 9) suggest, if, rather than being an essentially contested concept, power is a key term in various analytical language games that analysts of society engage in, then it behooves them to make clear how they are using the concept analytically rather than merely making normative statements. Given this, it is better to eschew discussion of essences being eternally contested. Instead, we should see power as a term that features in many related but distinct language games that, in Wittgenstein's (1967) terms have only limited family resemblances. Hence, some language games will center on domination, and others on power as productive of subject dispositions. The different concepts of power are tools with which to do things. Just as one would not have a toolbox comprising only hammers so that every problem becomes a nail to be hammered, so one would not work with an omnibus concept of power but would draw on different language games in different contexts of and for explanation and understanding. It is this understanding that characterizes Clegg's (1989) account of the different circuits of power through which empirical action might move and still be considered as power. Lacking an essence, power might be conceptualized in a manner that suits the task at hand, drawing on different traditions of analysis embedded in distinct language games that become more or less tangled up with each other in practice (see Clegg, Courpasson and Phillips 2006; Clegg and Haugaard 2012; Haugaard and Clegg 2012 for examples.).

Conclusion

In conclusion, we may note that in the genealogy of power that has been constructed here, power is not defined as only one thing, or in one set of terms. The terms shift with debate but there is a family resemblance among them. The emphases have changed with the values underlying scholarship. Lukes' importation of the Gramscian notion of hegemony seemed to take us a long way from the political communities that Dahl studied with such methodological scruples. Laclau and Mouffe's introduction of Foucault to the debate, somewhat surprisingly, brings debate back full circle to issues of political community because of the centrality their conception of power placed on discourse and identity. The theme of the relative autonomy of political processes dominated the late work of Foucault and was taken up empirically by Flyvbjerg. Thus, nearly 50 years after the Community Power Debate first kicked off contemporary sociological interest in the conceptual relation of power and society, the concepts have come back to their empirical point of departure, but they are much richer and more sophisticated than when they first embarked on that journey, because the family of power concepts has grown more sophisticated and developed more branches over that time.

Abstract

The study of the related concepts of power, politics, and influence in organizations has been a topic of interest for well over a century, with research expanding considerably in the last several decades. Power, politics, and influence are fundamental, and effectively ubiquitous, components of organizational life, serving to help explain how individuals act on their environments and interact with other individuals in organizations. This article briefly covers the existing knowledge of power, politics, and influence in organizations through a discussion of seminal works in these areas. Emerging areas of study and directions for future research are also discussed.

Power, Politics, and Influence: Historical Perspective and Literature Review

The History of Power, Politics, and Influence

Power, politics, and influence all represent components of human agency, which acknowledge that rather than being characterized as simply passive reactors to their contexts, individuals are active creators of their environments. Theories of human agency suggest that people act on their environments in ways that create, transform, preserve, and even destroy it, and they also act on themselves to adapt to contextual conditions (Bandura, 2006). As such, this implies the proactive initiation of goal-directed behavior.

The study of influence is perhaps the oldest experimental paradigm in the behavioral sciences, dating back to Triplett's (1898) investigation demonstrating that cyclists performed better in the presence of other cyclists than when alone (i.e., thus initiating the early underpinnings of the subsequently developed theory of social facilitation). Of course, many would date the study of influence even further back, to the sixteenth-century works of Niccoló Machiavelli (e.g., *The Prince*), which, among other things, illustrated how to gain and maintain political power. Machiavelli's work was likely one of the first to break from an abstract view of ideal ethics and political behavior, and instead focus on the effective truth of how power is amassed and preserved.

Nearly four centuries later, Dale Carnegie's self-help book *How to Win Friends and Influence People* brought the idea of influence into popular press, and predated much of the academic work in organizational politics and influence by decades. The tenants of the book were rooted in amicable and sincere interpersonal influence tactics and were applied to both professional and personal venues. Specifically, the book discussed the fundamentals of handling people, techniques to make people like you, ways to win people over to your way of thinking, and how to manage change within others. With over 30 million copies sold worldwide, there is no doubting the reach of Carnegie's message, and this work is recognized across disciplines by a wide variety of practitioners and academics alike. Carnegie's book drew attention to the role of social influence tactics in people's everyday lives and helped spawn the academic investigation into power, politics, and influence in organizations. This article will continue with a review of the academic literature that exists and provide some directions for future investigation.

Literature and Reviews of Power, Politics, and Influence

In the same year as Carnegie's classic mentioned earlier, Lasswell (1936) defined politics as "who gets what, when, and how," and argued that it was the manner in which aspects of the environment were manipulated that predicted success. Furthermore, Lasswell was one of the first scholars to identify and discuss the key role of social astuteness and influence execution as a determinant of the success of influence attempts (Almond, 1987). Twenty-five years later, Burns (1961) conducted one of the first scholarly discussions of politics in organizations. He suggested that organizations represent arenas or systems where competitions are staged by members for valued resources.

Over time, scholarly interest in power, politics, and influence in organizations has continued to flourish. This has provided the field with a rich collection of ever-expanding research examining these three aspects of the organizational sciences. Just some of what has been learned about power, politics, and influence is reported here. We encourage readers to explore the wealth of other published work on these topics, beyond the classics and reviews mentioned.

Power in Organizations

French and Raven's (1959) work examined The Bases of Social Power by conceptually deriving logical bases for social influence and psychological change, which are dependent on the relationship between the person and social agent. From this relationship, they developed five different bases of power. Expert power states that the social agent has knowledge above and beyond that of the person. Referent power refers to a situation where a person or people share a high level of identification with a social agent. Legitimate power implies that the social agent has a higher hierarchical standing than the person. Coercive power is used when a social agent is able to exert some sort of harm on the person, which is counter to reward power, where the social agent is able to reward the person for a specific performance.

Emerson (1962) sought to corral the contemporary literature on power-related concepts and derive a simple but

 http://dx.doi.org/10.1016/B978-0-08-097086-8.22027-8

generalizable theory of power through social relations. This theory gave no attention to trait or contextual factors and instead examined the power–dependence relationship between actors. Emerson reasoned that power and dependence between actors has a reciprocal nature, and the theory at its rudimentary level states that power is equal to the dependence of actor A on actor B. This dependence is positively related to motivational investment toward goals that are mediated by the other party. When there is an imbalance in this power and dependence, such that the dependence of actor A on actor B, moderated by the motivational investment of a goal, becomes greater than or less than the dependence of actor B on actor A, then one is said to have power over the other. By definition, power does not exist without the property of resistance, which occurs when an actor yields to something he or she would normally resist in an effort to work toward a treasured goal.

Emerson (1962) theorized that there are costs associated with one party meeting the demands of the other party, and that actors employ strategies to reduce these costs. Generally, these costs consist of value or identity shifts that make the process of meeting the other person's demands less painful for the dependent. Cost reduction strategies are, by definition, not necessarily associated with balancing operations, which specifically aim to change the balance of power rather than psychologically facilitating the demands of the more powerful actor. There are four balancing operations that bring a two-party interaction back toward power equilibrium. The first two are reducing motivational investment in goals moderated by the more powerful actor and finding alternative sources of gratification for those goals. The third balancing operation is for the more powerful actor to increase motivational investment in a goal moderated by the less powerful actor, which is contingent on the fourth operation that no alternative source of gratification is available for the more powerful agent to achieve this goal.

Utilizing the idea of power as the ability of A to modify B without modifying his or her own behavior, Schein (1977) conceptualized the bases of individual power, the intent of a powerholder, and the means used by a powerholder. Building upon French and Raven's (1959) sources of power, Schein noted that individuals use power in self-serving ways to "a) obtain more power, b) maintain current power, and c) eliminate other's power" (p. 66). All actions and movements within an organization are to achieve more power, and often are accomplished through behaviors that can be either congruent or incongruent with the organization's goals. Behaviors that are incongruent were deemed political by Schein, and involve the use of overt or covert actions that align with the individual's current power bases. Which power bases are utilized and the type of behaviors selected often will be determined by the intent of the individual.

Politics in Organizations

Between the mid-1970s and the mid-1980s, several scholars proposed political perspectives on organizations (i.e., Mintzberg, 1983; Pfeffer, 1981; Porter, 1976; Salancik and Pfeffer, 1974). These political perspectives seemed to share in common the view that to obtain power in organizations, it took the skillful use of political behavior and/or influence tactics/strategies, which, Pfeffer and Mintzberg argued, required political skill. The recent emphases by scholars in this area today have maintained the intertwined nature of these constructs, demonstrating the commonalities or how the different components work together synergistically. For example, Pfeffer (2010) has argued that power is obtained through the skillful selection and execution of mechanisms of influence (i.e., politics or political behavior and influence tactics), which require political skill to ensure effectiveness in execution and goal attainment.

Salancik and Pfeffer (1974) were among the first scholars to examine power above the individual level by examining subunits in university academic departments. They found that the departments able to acquire the most outside resources (i.e., grants and other funding sources), also received the greatest amount of scarce resources from the university. Indeed, the "power derived from acquiring resources is used to obtain more resources, which in turn can be employed to produce more power – the rich get richer" (p. 470).

Taking a more structural approach, Astley and Sachdeva (1984) synthesized what they believed to be a fairly fragmented theoretical literature on organizational power by developing a theoretical model that incorporated three structural sources of power. Hierarchical authority is grounded in the conception of power being inherent in an official role or position. Resource control suggests that power can come from the ability to distribute or withhold vital resources. Finally, network centrality yields power when a person holds a central network position within multiple interdependencies, thus making him or her a conduit to resource facilitation. After running pair-wise comparisons among the three sources of power, these authors concluded that there was a mediating effect of the third, suggesting a more interconnected theoretical relationship.

Influence in Organizations

This previous theoretical work laid the framework for the empirical study of intraorganizational influence tactics by Kipnis et al. (1980). Whereas most research during this time focused on executive influence, this piece focused on the political influence tactics employed at lower levels of the organization by middle managers. Using content analysis, they identified eight dimensions of influence: assertiveness, ingratiation, rationality, sanctions, exchange, upward appeals, blocking, and coalitions. This study not only provided practical insight into how organizational agents influence each other, but also tangentially supported the notion that influence in organizations is not just bound by leadership. Indeed, there are political underpinnings to multiple levels of the organization.

A core component of how individuals may exert influence, participate successfully in politics, and gain power is through the utilization of select influence tactics known as impression management techniques. Quite literally, impression management represents the behaviors in which actors engage to manage the identities they have selected or been assigned by others by way of influencing the impressions others have of them (Tedeschi and Melburg, 1984).

Although there are a variety of impression management tactics available, they can be described primarily in terms of two dimensions: defensive-assertive and tactical-strategic (Tedeschi and Melburg, 1984). Assertive impression management deals

mostly with establishing an identity, and thus, tends to be active in nature. On the other hand, defensive impression management is more reactive, occurring when actors face some sort of issue or threat to an identity. Tactical impression management is geared toward short-term objectives, while strategic impression management is long-term focused. All impression management techniques essentially can be classified along these two dimensions, so tactics can be described as defensive-tactical (e.g., apologies), defensive-strategic (e.g., learned helplessness), assertive-tactical (e.g., ingratiation), and assertive-strategic (e.g., status).

Liden and Mitchell (1988) examined ingratiation, a form of impression management common in organizations and popular in organizational research, a major component of many social influence attempts, and a component of social interaction processes. They defined ingratiation as behaviors employed by a person to make himself or herself more attractive to another. The linear conceptualization of the ingratiation process explores the motivation of ingratiation, choice of ingratiation strategy, ingratiation behavior, target reaction, and outcomes. This portion of the model is impacted by situational determinants.

Ingratiation behaviors are motivated by a need to be liked stable trait, or a situational opportunity to defend or promote one's self. A risk assessment would determine the strategy used to ingratiate the target, as there are potential costs associated with ingratiatory behavior. If the ingratiator chose to move forward, three distinct behaviors are possible. Target-directed behaviors represent interpersonal exchanges between the ingratiators and targets, and are meant to make targets feel good about themselves. Self-presentation deals specifically with impression management of one's self, and could include positive self-description or, in a more defensive situation, apologetic language. Third-party tactics involve influencing a knowing or unknowing assistant to convey positive messages about the ingratiator to the target. The targets' perception will depend upon whether the attempt is perceived as assertive or defensive, and whether it is sincere or manipulative. At the time of this study, little was known about the short- and long-term outcomes of ingratiation behaviors.

Leary and Kowalski (1990) described impression management (i.e., also referred to as self-presentation) as the process by which people control the impressions others form of them. They compiled the relevant impression management literature and developed a two-component model that conceptualizes impression management as two distinct processes: impression motivation and impression construction. Impression motivation is defined as the degree to which people are motivated to control how others see them, which is impacted by both situational and dispositional factors. In their model, a host of factors are examined using three distinct dimensions. Goal relevance of impression is the extent to which impressions have an impact on a goal or set of goals. The value of desired goals is rooted in the well-accepted notion that there is a positive relationship between the importance of a goal, and one's motivation to do so. Finally, if there is a high perceived discrepancy between desired and current images, people will tend to be motivated to act in a way that changes these perceptions.

The second component of the model addresses how impressions are constructed. Some criticisms of the impression management models stem from the notion that people are trying to deceive the target of their impression management. While this can be the case, it is also true that individuals simply want to portray themselves in a positive light, and thus their self-concept is an important factor in determining what type of impression to build. When individuals feel the need to fabricate or embellish aspects of themselves, they will draw upon desired and undesired identity images to construct an impression. Expectations about how an individual in a particular role should behave create a role constraint that guides the observable behaviors of a person and thus impacts impression formation. Much literature exists suggesting that impressions often are tailored to meet the target's values in attempts to gain favor, and even may do so by portraying values with which senders may not agree as long as they are compatible with the target's values. Finally, impression strategies are constructed based upon the senders' perception of how they are currently viewed by the target.

So, as noted, power, organizational politics, and social influence represent distinctive yet overlapping areas of theory and research in the organizational sciences that have been studied actively for decades. Furthermore, periodically over those years, many comprehensive reviews of these literature have been published, some selectively reviewing just the work regarding each separate construct, and other recent reviews that incorporate two or even all three of the constructs together. As a result, collectively and individually, we as a field know quite a bit about power (e.g., Emerson, 1962; French and Raven, 1959; Mintzberg, 1983; Salancik and Pfeffer, 1974), organizational politics (e.g., Ferris et al., 2002a,b; Ferris and Hochwarter, 2011; Silvester, 2008), and social influence (e.g., Kipnis et al., 1980; Leary and Kowalski, 1990; Liden and Mitchell, 1988; Tedeschi and Melburg, 1984).

Power, Politics, and Influence in Action

More recently, research in this area has begun examining how individuals can effectively employ their power, politics, and influence. Among the most prevalent explanations for this effectiveness is the construct known as political skill (Ferris et al., 2012). Originally described in the 1980s (e.g., Mintzberg, 1983; Pfeffer, 1981), political skill did not start to catch on in continued scientific work until the late 1990s and mid-2000s with the development of the Political Skill Inventory, and the theoretical development of the political skill construct (Ferris et al., 2007).

Political skill is defined as "the ability to effectively understand others at work, and to use such knowledge to influence others to act in ways that enhance one's personal and/or organizational objectives" (Ferris et al., 2007: p. 291). The construct consists of four dimensions: social astuteness, interpersonal influence, networking ability, and apparent sincerity. These four dimensions together form the overall construct, which is a particular form of what is known as a social effectiveness construct. These sorts of constructs are individual differences that each person possesses, to a greater or lesser degree, which help to facilitate easy and successful social interactions for those who score highly in them, through the dimensions listed earlier.

Social astuteness allows for keen understanding of the other people and social situations around an individual.

Interpersonal influence deals with an individual's ability to be flexible, to adapt to particular situations, and be able to still effectively influence others. Networking ability is quite literally how well an individual creates, maintains, and utilizes valuable contacts or networks of contacts. Finally, apparent sincerity might be the most important of the dimensions because, without this, success with any of the other dimensions is much less likely. Apparent sincerity deals with politically skilled individuals appearing genuine or honest, regardless of their underlying intentions. Influence attempts made when the target of the attempt does not believe the intentions of the influencer are sincere are much less likely to be successful than they would be if the influencer has a high political skill and target believes the influencer has no ulterior motives (Ferris et al., 2012).

Political action and the acknowledgment of politics in organizations are inherently perceptual. An action that one target of influence might interpret as politically motivated for a negative cause might be interpreted in a positive manner by another target, and might even go unnoticed and not deemed political by yet another target. The perception of organizational politics impacts organizations in many ways. Because of this, the antecedents, consequences, and moderating factors of the perceptions of organizational politics have received a greater amount of attention over the past few decades (e.g., Ferris et al., 2002a).

Researchers have found organizational influences (e.g., centralization of power, formalization, hierarchical level), work environment influences (e.g., advancement opportunities, feedback, interactions with coworkers), and personal influences (e.g., Machiavellianism, affect) to directly lead to individuals' perceptions of politics in organizations, which are then associated with a number of outcomes. Perceptions of politics have been found to be positively related to job anxiety, organizational cynicism, organizational withdrawal, and political behavior, among many others, and negatively related to job satisfaction, job performance, and organizational commitment (Ferris et al., 2002a).

The direct relationships between the antecedents of perceptions of organizational politics listed earlier and its consequences can be moderated by many individual variables, such as age, gender, self-efficacy, perceived control, and understanding of organizational politics. Thus, these moderator variables can result in considerable variation across individuals regarding how politics is perceived and the consequences such perceptions produce. What one might view as a threat and intimidating political landscape could be perceived as an environment full of exciting opportunities by another. The political skill of an individual is yet another moderating factor that can impact how politics is viewed and approached by individuals. Politically skilled employees are better able to navigate political settings, would have much different perceptions of an organization's political atmosphere, and thus would be able to work through the politics to ensure positive consequences (Ferris et al., 2002a).

Measurement of Politics in Organizations

The fact that political behavior and the political environment of organizations are perceptual and can change from person to person is one of the factors associated with the difficulty measuring power and politics in organizations. As mentioned earlier, perceptions of politics can vary widely from person to person depending upon certain demographic, personality, and skill-set factors. Thus, determining a 'true' level of politics within an organization is likely impossible, as the construct can be construed as largely perceptual in nature.

Other issues exist when attempting to measure political behavior. In the organization sciences in general, reviewers and methodologists often criticize the prominent use of self-report measures. Due to the tainted general attitude toward politics, self-report measures are even more of an issue due to social desirability bias. Many of the items in existing measures are negatively toned (Ferris and Hochwarter, 2011), and because of this negative tone, individuals completing a survey who prefer to view themselves in a positive light would be less likely to accurately admit they partake in certain behaviors deemed as political. Additionally, individuals in organizations who are politically skilled may not wish to accurately complete surveys that they feel could inhibit their functioning within the organization's political network.

A final issue with measurement revolves around the lack of agreement on what constitutes political behavior. Many authors have acknowledged the definitional issues that persist in the power and politics literature (e.g., Ferris et al., 2002a; Silvester, 2008; Ferris and Hochwarter, 2011). Some definitions focus primarily on the negative aspects of political behavior in organizations, whereas others acknowledge that good can result and take a more neutral stance. As the literature on power and politics expands, it is important for authors to focus on aspects of these constructs that are clear and observable.

It is impossible to measure a construct that does not have a clear definition, so by providing accurate and precise definitions scholars can encourage future research that builds on previous work in a constructive manner. The measurement of power and politics has many issues that require attention, from the development of valid measures to the development of better methodologies. In order to develop these measures and methodologies, clearer and more precise definitions of what is actually being studied are necessary.

The study of power, politics, and influence in organizations has received extensive attention in many types of organizations, both large and small, public and private. However, it is somewhat ironic that organizational scholars have paid very little attention to partisan politics: the study of professional politicians, the skills they possess, and the ways they operate within their professional roles (Silvester, 2008). Some researchers have suggested that the roles of professional politicians and regular workers are very different, but little evidence exists about such differences. Silvester noted that more consideration should be given to how the study of politicians at work and political activity in organizations may overlap. Political behavior certainly is prominent in politicians, and although the behavior is expected and sanctioned for politicians, they still need to effectively use their power and influence to satisfy their various constituents. Like traditional workers in organizations, they must monitor and navigate their environments and utilize political skill to succeed. Silvester suggested that further synthesis of the bodies of research constructed by sociologists and political theorists could greatly contribute to the study of politics in organizations and vice versa.

Research on Power, Politics, and Influence: Key Issues and Directions

Rather than simply continuing to reiterate what other fine reviews already have stated, we focus our paper on several important issues in the area of power, politics, and influence on which we need much more research. We present these issues in no particular order of importance.

Nonlinear Effects of Influence

Although a significant amount of research has been devoted to examining social influence and its effects as a linear process, a discussion of the potential nonlinear effects of influence in the organizational sciences is warranted. All too often, antecedent variables are presented, theorized, and tested as linear in their relation to organization outcomes (e.g., job performance, job satisfaction), but, in reality, a growing number of empirical studies have demonstrated that variables believed to have a positive, linear relationship with these outcomes actually are associated with negative outcomes and effects (Pierce and Aguinis, 2013). This nonlinearity is likely no different for much, if not all, of the research in power, politics, and influence.

Pierce and Aguinis (2013) describe this pervasive nonlinearity as the too-much-of-a-good-thing effect (TMGT effect). They propose that all linear, positive relationships eventually reach a context-specific downturn, and level-out or become negative at high levels or when taken too far, resulting in a curvilinear relationship (e.g., an inverted U-shape). This effect was proposed to account for the seemingly paradoxical relationships found in a variety of relationships.

In the power, politics, and influence literature, the linearity of antecedents' relationships with outcomes cannot be as quickly inferred as it might have once been. An example of this can be found in the work of Ames and Flynn (2007), who found a curvilinear relationship between assertiveness and leadership effectiveness. Leadership was less effective at both the high and low extremes of assertiveness, tipping down to increasingly less effectiveness at a context-specific inflection point. Evidence such as this and the meta-theoretical framework of the TMGT effect suggest that there is actually an optimal level for many constructs that is not always the highest, or most extreme, values. In many instances, as in the one illustrated by Ames and Flynn, more is not always better.

Power, Politics, and Influence as Positive (Not Simply All Negative)

Despite the stigma attached to the word politics, not all behaviors dealing with power, politics, and influence are inherently negative. Notwithstanding this widespread misunderstanding, there has been very little research done on the positive aspects of these constructs. Hochwarter (2012) is a notable exception, and his review leads our discussion of the positive, or dualistic, aspect of power, politics, and influence. Continued research into the positive aspects of these areas is presented as a clear direction for future research.

The Greek philosopher Aristotle once noted that "man is by nature a political animal"; an observation that advocates that political behavior as ingrained in who we are as a species. Indeed, evolutionary research suggests that the ability to acquire and manage resources, oftentimes with the influence and assistance of others, will separate those who thrive from those who perish. Whether this phenomenon is bread out of our DNA, or through social construction, it is clear that an organizational actor's survival is predicated on the ability to properly acquire and manage contextually relevant resources (Hochwarter, 2012).

In practice, organizations are a collective of actors working in a hyperchanging environment, who hold asymmetrical resources, which cause significant uncertainty and situational anxiety. Political behaviors provide the ability to adapt in these environments, and it has been shown that those organizational actors who can skillfully swap, acquire, or share resources or information among other organizational actors have been able to reduce ambiguity and thus reduce associated stress levels.

Political behavior also can be effectively employed to combat injustices within the organization. Organizational actors at all levels can utilize political behaviors to bring balance to an untold number of unjust situations such as discriminatory promotion practices, workplace harassment, and compensation. While it is acknowledged that self-serving political behavior has the power to create or maintain unjust situations, it is also the case that personal orientation and context can lead to equally powerful instances of other-serving political behaviors aimed at balancing injustices that negatively impact other actors who reside at different or identical levels of the organization.

Perhaps most famously, political skill has been positively linked with job performance and career success (Hochwarter et al., 2007; Ng et al., 2005). This relationship may once again conjure up images and anecdotes of organizational actors schmoozing and backstabbing their way to success at the expense of others, and although this can be the case, there are many demonstrated positive political behaviors that improve personal outcomes. The initial stages of any young career or contextual situation can be classified as weak and ambiguous, granting the newcomer very few cues about how to act appropriately and effectively. For example, proactive employees who effectively engage in information-seeking activities are able to reduce information incongruences, and build task-specific skills, as well as learn to properly self-regulate within the organizational setting.

The previous discussion suggests many instances and situations in which political skill, power, and influence are able to further the cause of the individual organizational actor, and the organization itself. There is immeasurable work to be done examining the positive aspects of these constructs. Hochwarter (2012) has suggested that a clear distinction be made between positive politics and other casual subordinate-benefitting activities, such as organizational citizenship behaviors. Additionally, the genetic, situational, and motivational antecedents of positive politics are yet to be explored. Fedor et al. (2008) proposed that research be done on the organizational actor's perception of political behavior and the resulting positive outcomes. Put simply, do the ends justify the means? Future research will hopefully answer these and other related questions and lead us to a more equitable and balanced understanding of organizational politics.

Conclusion

Power, politics, and influence represent key components of human agency, and they play important roles in interpersonal interaction in organizations and in daily life. Their importance has been recognized for hundreds of year, but it is just in the past 30 years that the academic investigation into these concepts' impact in organizations has received great attention. We have attempted to summarize and present the majority of the central findings involving power, politics, and influence in organizations, but, for sake of concision, much great research has been omitted. We have also presented some areas of politics in organization that we believe deserve greater attention and will be rewarding paths of investigation. In sum, although much has been done to investigate and understand the role of power, politics, and influence in organizations, there is still much to be done. We call for scholars to continue to build upon previous findings and provide greater insight into the role these constructs have in organizational life.

Practical Reasoning: Philosophical Aspects

RJ Wallace, University of California Berkeley, Berkeley, CA, USA

Abstract

Practical reasoning is reasoning that aims to resolve the question of what an agent is to do. This article considers the theoretical commitments of reasoning of this kind, as well as the motivational constraints to which it is subject. How is it possible for reasoning to engage the will? Can we make sense of practical reasoning within a broadly naturalistic conception of agents and the world? What are the distinctive forms that practical reasoning can take?

Practical reasoning is reasoning that aims to resolve the question of what one is to do. Such reasoning is practical in at least two senses. First, it is practical in its subject matter, insofar as it is concerned with human *action*. But it is also practical in its issue, insofar as reflection about action can itself directly move people to act. Reasoning of this kind raises two sets of philosophical problems. One concerns the question of how reflection can succeed in being practical in its issue. What assumptions must be made both about agents and about the processes of reasoning they engage in to make sense of the fact that such reflection can give rise to action? Can justice be done to this fact while preserving the idea that practical reasoning is genuinely a form of reasoning? A second set of issues concerns the content of the standards that are brought to bear in practical reasoning. Which norms for the assessment of action are binding on us as agents? Do these norms provide resources for critical reflection about our ends, or are they exclusively instrumental? Under what conditions do moral norms yield valid standards for reasoning about action? The first set of issues is addressed in the following three sections, while the last two sections cover the second set of issues.

Practical and Theoretical Reasoning

Practical reasoning takes place from a distinctive standpoint. When agents deliberate about action, they think about themselves and their situation in characteristic ways. What are some of the salient features of the practical point of view?

One way to interpret this point of view is to contrast it with the standpoint of theoretical reflection. Theoretical reflection is sometimes understood as reasoning about questions of explanation and prediction. Looking backward to events that have already taken place, it asks why they have occurred; looking forward, it attempts to determine what is going to happen in the future. In these ways, theoretical reflection is concerned with matters of fact and their explanation. Furthermore it treats these issues in impersonal terms that are accessible (in principle) to anyone. The natural and social sciences can be viewed as giving paradigmatic expression to theoretical reasoning, so construed.

Practical reasoning, by contrast, takes a distinctively normative question as its starting point. It typically asks, of a set of alternatives for action none of which has yet been performed, what one ought to do, or what it would be best to do. It is thus concerned not with matters of fact and their explanation, but with matters of *value*, of what is to be done. In practical reasoning, agents attempt to assess and weigh their *reasons for action*, the considerations that speak for and against alternative courses of action that are open to them. Moreover they do this from a distinctively first-personal point of view, one that is defined in terms of a practical predicament in which they find ourselves (individually or collectively – people sometimes reason jointly about what they should do together; *see* Joint Action).

There is, however, a different way of understanding theoretical reasoning, stressing the parallels rather than the differences between the two forms of reflection. According to this interpretation, theoretical reflection too is concerned with a normative rather than a factual question, namely with the question of what one ought to believe. It attempts to answer this normative question by assessing and weighing reasons for belief, the considerations that speak for and against the particular conclusions one might draw about the way the world is. Furthermore, it does this from a standpoint of first-personal reflection: the stance of theoretical reasoning in this sense is the committed stance of the believer, not the stance of detached contemplation of one's beliefs themselves (Moran, 2001). Seen in this way, the contrast between practical and theoretical reflection is essentially a contrast between two different systems of *norms*: those for the regulation of action on the one hand, and those for the regulation of belief on the other.

Theoretical reflection, interpreted along these lines, addresses the considerations that recommend accepting particular claims as to what is or is not the case. That is, it is reasoning with an eye to the truth of propositions, and the reasons for belief in which it deals are considerations that speak in favor of such propositions being true, or worthy of acceptance. Practical reasoning, by contrast, is concerned not with the truth of propositions but with the value of actions. The reasons in which it deals are considerations that speak in favor of particular actions being good, or worthy of performance in some way. This difference in subject matter corresponds to a further difference between the two kinds of reasoning, in respect of their consequences. Theoretical reflection about what one ought to believe produces changes in one's overall set of beliefs, whereas practical reason gives rise to action; it is, as noted earlier, practical not only in its subject matter, but also in its issue.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63063-5

Two observations are in order about this side of practical reasoning. First, the contrast just drawn might suggest that there is a categorial difference in the effects of theoretical and practical reasoning, insofar as the former produces changes in our mental states, whereas the latter gives rise to bodily movements. But this would be misleading. Practical reasoning gives rise not to bodily movements per se, but to intentional actions, which are intelligible as such only to the extent they reflect our mental states. It would thus be more accurate to characterize the consequences of both theoretical and practical reasoning as *attitudes*, noting that the former leads to modifications of our beliefs, whereas the latter leads to modifications of our *intentions* (Harman, 1986; Bratman, 1987).

Second, in neither case do the modifications in question occur infallibly. There is room for *irrationality* both in the theoretical and the practical sphere, which in its strongest form involves a failure to acquire the attitudes that one acknowledges to be called for by the reasons one has reflected on. Thus a person might end up watching another hour of television, while judging that it would be better on the whole to go back to work. Practical irrationality of this latter kind is known as *akrasia*, incontinence, or weakness of will, and its possibility makes clear that practical reasoning is not automatically practical in its issue. A better way to represent the consequences of practical reasoning would be to say that it generates appropriate intentions to the extent an agent is rational (Korsgaard, 1996; *see* Irrationality (Philosophical Aspects)).

Naturalism and Normativity

The connection of practical reasoning with intentional action raises large questions about its credentials as a genuine form of reasoning. As noted earlier, intentional action is not mere bodily movement, but reflects a mental state of the agent, viz. intention. To be in this kind of mental state is to have a goal or aim of some kind, which one seeks to realize through one's action. Intention seems in this respect to be strikingly unlike belief. The propositions that give the content of beliefs have a representative function; they aim to fit the way the world is, so that if one discovers that the world is not how one previously took it to be, one's belief will automatically be modified in the process. With intentions, however, matters are otherwise (Smith, 1987). The intention to go shopping on Tuesday, for instance, is not a state that would or should be abandoned upon discovering that one has not (yet) gone shopping on Tuesday; rather the person with such an intention will ordinarily try to bring the world into alignment with the intention, by going shopping when Tuesday comes around. Intentions are in this way more like blueprints than like sketches of an already completed structure.

Reflection on this contrast between belief and intention has led some philosophers to ask whether practical reasoning might not be something of a misnomer. The concern, in a nutshell, is how processes of thought that count as genuine reasoning could by themselves generate states with the peculiar, nonrepresentative function of intentions. Reasoning seems to consist of cognitive operations, whereas intentions are distinctively noncognitive states, insofar as they do not aim to reflect the way things happen to be in the world.

Expressivist accounts give voice to this skeptical attitude about practical reasoning. These accounts offer interpretations of the normative language that distinctively figures in practical reflection about action. As was seen in the first section, such reflection is an attempt to assess an agent's reasons for acting in one way or another; conclusions about such reasons are characteristically expressed in claims about what it would be *good* to do, or about the actions that one *ought* to perform. According to the expressivist, however, such claims do not represent genuine cognitive achievements, judgments that are literally capable of being true or false. Rather they give expression to desires, sentiments, and pro-attitudes, the kinds of noncognitive state that motivate people to action. Only if normative assertions are understood in this way – so the expressivist contends – can sense be made of the capacity of practical reflection to generate states with the peculiar structure and function of intentions.

Expressivism in this form can be seen as a naturalistic interpretation of practical reasoning, one that is appropriate to the enlightened commitments of the modern scientific world view. It is naturalistic metaphysically, insofar as no assumptions need be made about the objective existence in the world of such questionable entities as values, norms, or reasons for action. If normative claims do not represent genuine cognitive achievements, then their legitimacy does not depend on our postulating a realm of normative facts to which those claims might correspond. It is also naturalistic psychologically, insofar as it promises explanations of intentional human behavior that are basically continuous with explanations of the behavior of non-human animals. In both the human and the non-human cases, behavior is seen as the causal product of noncognitive attitudes, operating in conjunction with the creature's factual representation of how things are in its environment. The difference is just that humans have much more sophisticated linguistic methods for giving voice to their motivating noncognitive attitudes. Indeed, many contemporary expressivists would contend that these expressive resources are sufficiently powerful to explain the features of practical reflection that initially give it the appearance of a genuine form of reasoning (Blackburn, 1998; Gibbard, 1990).

Other philosophers remain unimpressed with these naturalistic explanations. One ground for dissatisfaction with them is the following. The expressivist strategy relies on an initial contrast between practical reflection and the genuine forms of cognitive activity characteristic of theoretical reasoning. There has to be some basic sense in which such discourse does not come up to the standards of authentic cognitive discourse in the literal sense; otherwise the contention that normative discourse is expressive rather than cognitive will lack any significant content. But the contrast between theoretical and practical reflection required for this purpose seems elusive. As was seen in the first section, theoretical reasoning is no less a normative enterprise than practical reasoning. It concerns itself with reasons for belief, the evidence and other considerations that speak for and against particular conclusions about the way things are in the world. In this respect, theoretical and practical reasoning would seem equally problematic from the naturalistic perspective – assuming, that is, that it leaves no place for such normative considerations as reasons. But if *naturalism* calls into question

the credentials of theoretical reason, it thereby undermines the contrast between genuine reasoning and noncognitive normative discourse on which expressivists themselves rely (*see* Emotion and Expression).

Reasons and Motivation

The capacity of practical reasoning to generate intentional action divides even those philosophers who agree in rejecting the expressivist strategy discussed earlier. Such philosophers are prepared to grant that there are reasons for action, and to accept the cognitive credentials of normative claims about such reasons. But they differ in their accounts of the truth conditions of these normative claims. Two approaches may be distinguished.

The first of these, frequently referred to as internalism, holds that reasons for action must be grounded in an agent's prior motivations (Williams, 1981). According to this position, a given agent s can have reason to do x only if x-ing would speak to or further some element in s's 'subjective motivational set.' There must be some rational route that connects s's x-ing with the subjective motivations to which s is actually already a subject; otherwise the claim that s has reason to x must be rejected, as false or incoherent. Behind this internalist position lies the idea that practical reasoning is practical in its issue. Internalists contend that sense can be made of the capacity of such reasoning to generate new intentions only if it is conditioned by motivational resources that are already to hand. Reasoning about action is a matter of working out the implications of the commitments contained in one's subjective motivational set. In this sense, *motivation* is prior to practical reason, and constrains it (though it might function as a background condition of practical reason, rather than a focus of attention for agents when they deliberate about what to do: Schroeder, 2007).

Externalists reject this assumption, contending that one can have reasons for action that are independent of one's prior motivations. Most of them agree that practical reasoning must be capable of generating new intentional actions, and hence of giving rise to motivation. They agree, in other words, that if agent s has reason to do x, it must be possible for s to acquire the motivation to x through reflection on the relevant reasons. But they deny that such reasoning must in any way be constrained by s's subjective motivations prior to the episode of reasoning. Practical reasoning is not exclusively a process of working out the implications of one's existing commitments; it is also an attempt to get clear about what it would objectively be good to do. Normative considerations of this kind are independent of one's prior motivations and can open up new motivational possibilities (Parfit, 1997).

Underlying this dispute are diverging approaches to the explanation of intentional action. Internalists are impressed by the differences between intentions and the cognitive states that figure in paradigmatic examples of theoretical reasoning. Pointing to these differences, they ask how practical reasoning can succeed in producing new intentions if it is not grounded in something of the same basic psychological type: a motivation or desire that is already part of the agent's subjective motivational equipment. Many externalists find this contrast between intentions and cognitive states overdrawn. They observe that we need to postulate basic dispositions of responsiveness to reasons to account for the capacity of theoretical reflection to generate new beliefs, and question why these same dispositions cannot explain the fact that practical reasoning is practical in its issue. Cognitive or not, intentions belong to the broad class of attitudes that are sensitive to normative judgments, and this may account for the capacity of practical reflection to give rise to new intentions (Scanlon, 1998). A third possibility is that intentions are products of the *will*, a capacity for self-determination distinct from the dispositions that render theoretical rationality possible. Depending on how it is developed, the theory of the will may offer a different way of accounting for the practical consequences of practical reflection, without assuming that reasons for action are grounded in an agent's subjective motivations (Wallace, 1999).

Instrumental and Maximizing Rationality

Among the substantive norms of practical reasoning, those of instrumental rationality appear least controversial. *Instrumental rationality*, in its most basic form, instructs agents to take those means that are necessary to achieve their ends. In the modern era, this form of rationality has widely been viewed as the single unproblematic norm of practical reasoning. The instrumental principle makes no assumptions about the prospects for rationally scrutinizing peoples' ends. Rational criticism of this kind would seem to presuppose that there are objective values, standards for assessment of ends that are independent from psychological facts about what people happen to be motivated to pursue. In keeping with the naturalistic attitude sketched in Section Naturalism and Normativity, however, it may be doubted whether such standards can be reconciled with the metaphysical commitments of contemporary scientific practice (*see* Value Pluralism). A world that is shorn of objective values or norms leaves no room for rational criticism of people's ends, but only for Weberian *Zweckrationalität*: the rational determination of means to the realization of ends that are taken as given, as a matter of psychological fact.

It is important to bear in mind, however, that instrumental rationality is itself the expression of an objective normative commitment. The instrumental principle tells us that we have *reason* to take the means that are necessary to achieve our ends; if the principle is valid, then people are open to rational criticism to the extent they fail to exhibit this kind of instrumental consistency, regardless of whether they want to comply with the principle or not. If naturalism really leaves no place for objective norms or values, it may be wondered how an exception can possibly be made for the instrumental norm. The consistent naturalist should perhaps reject even *Zweckrationalität* in favor of a skeptical attitude toward practical reasoning in all its forms (Hampton, 1998). Further questions can be raised about the plausibility of the instrumental norm as a self-standing principle of practical reason. The norm says that one should take the means that are necessary to achieve one's ends. But how can the fact that a given means is necessary, relative to some end, give a person reason to choose the means, if the end is not itself something it would be good to achieve in some

way? The instrumental principle seems to function as a binding standard for practical reasoning only if it is taken for granted that there are additional, independent standards for the assessment of our ends (Korsgaard, 1997).

Many proponents of the instrumental principle would agree that it does not generate reasons for action. The fact that a given means is necessary, relative to one's given ends, is not a reason to take the means. The instrumental principle functions, rather, as a structural requirement on one's attitudes (Broome, 1999). Thus, suppose one intends end E, and believes (truly) that E can be achieved only if one intends to do M. It appears that there are two ways in which one could revise one's attitudes in response to these considerations, compatibly with the instrumental principle: one could form the intention to M, or one could abandon one's original intention to E. The instrumental principle, considered in itself, is indifferent as between these two possibilities; it should be understood as a wide-scope requirement, governing combinations of attitudes, rather than a source of detachable normative conclusions about what one has reason to do. (Modus ponens represents a similar rational requirement in the domain of theoretical reason, governing combinations of beliefs.)

Rational requirements of this kind have recently become a subject of intensive philosophical debate. The idea that there are structural requirements on our attitudes appears to be common ground among philosophers who differ significantly in their views about the nature and scope of practical reason. It is accepted by most Humeans, for instance, who believe that there is no scope for the rational criticism of individual ends, and also by Kantians, who think that the requirements of reason ultimately constrain us to choose in accordance with the moral law. From the perspective of practical and theoretical deliberation, we commonly grant the force of these structural requirements, acknowledging a kind of rational pressure to bring our beliefs and intentions into compliance with the instrumental principle and other standards of consistency and coherence.

Many philosophers take such structural requirements at face value, granting that practical reason is rightly governed by and responsive to these wide-scope demands. But what is the relation between structural requirements of this kind and our reasons for action and belief? One view, held in common by Humeans and by some Kantian constructivists (see Section Naturalism and Normativity), is that reasons are fundamentally derivative from rational requirements. What one has reason to do, on this view, is what one would desire or intend to do if one was fully rational (i.e., fully in compliance with the wide-scope structural requirements that govern one's attitudes in combination).

For those who do not share this reductionist view, however, the status of rational requirements becomes more puzzling. One might hold that practical reason is ultimately answerable to two different kinds of constraints: to rational requirements on the one hand, and to independent facts about what one has reason to do on the other hand. But this position is potentially unstable. Once the independence of structural requirements from normative reasons is made clear, it is no longer obvious why we should care about whether our attitudes do or do not comply with the structural requirements (Raz, 2005). On this view, there is nothing wrong with failing to take the necessary means to your end, unless the end itself is one that you have compelling reason to pursue. More generally, it has been argued that there are no independent requirements of structural rationality at all, and that the appearance of such requirements within the deliberative point of view can be explained by substantive features of the reasons to which both practical and theoretical reason are ultimately and properly responsive (Kolodny, 2005).

Humean proponents of structural approaches to practical reason have attempted to make room for the rational criticism of individual ends, without departing from the spirit of *Zweckrationalität*, by expanding their view to encompass the totality of an agent's ends. Thus, even if there are no values that are ultimately independent of an agent's given ends, it would appear possible to criticize particular intrinsic desires by reference to others in the agent's subjective motivational set. An agent's desire for leisure, for instance, might be subordinated insofar as its satisfaction would frustrate the realization of other goals that are subjectively more important to the agent. Practical reasoning, it might be suggested, is a holistic enterprise, concerned not merely with the specification of means to the realization of individual ends, but with coordinated achievement of the totality of an agent's ends.

Many philosophers view this holistic perspective as the most fruitful way of conceptualizing the tasks of practical reasoning. It defines an important and difficult problem for practical reasoning to solve, without departing from the metaphysically modest assumption that there is no court of appeal for the rational criticism of an agent's ends that is independent of those ends themselves. The most sophisticated and influential expression of this holistic perspective is the *maximizing* conception of rationality. According to the maximizing conception, the fundamental aim of practical reasoning is to determine which course of action would optimally advance the agent's complete set of ends. Thus it has been suggested that the rational action is the one whose subjective expected *utility* – reflecting both the utility of possible outcomes, from the agent's point of view, and the agent's beliefs about the probability of those outcomes – is the highest.

The maximizing conception of rationality finds its most complete expression in *decision theory* and in the theory of *rational choice* (as developed, for instance, in economics). These disciplines articulate with mathematical precision the assumption that one is acting rationally to the extent one does what is likely to bring about the best state of affairs, given both one's preferences and one's beliefs about the probable consequences of the alternatives that are open to one. Proponents of these theories often claim for them the additional advantage of empirical adequacy, contending that they are flexible enough to accommodate the full range of behaviors that human agents engage in, both within the marketplace and outside of it. Especially if one operates with the notion of 'revealed preferences' – preferences, that is, that are inferred solely on the basis of actual behavior – then virtually anything an agent might choose to do could be interpreted as an attempt to maximize expected utility. Decision theory, on this account of it, becomes an all-encompassing framework for the interpretation of human behavior, according to which agents are always striving to produce outcomes that would be optimal, relative to their

preferences and beliefs (*see* Rational Choice Explanation: Philosophical Aspects).

If decision theory is interpreted in this way, however, then its relevance to the understanding of practical reasoning begins to seem correspondingly tenuous. Maximizing rationality initially looks to be a norm of practical reflection. In this guise, its appeal lies in the idea that there can be rational requirements on action, stemming from the totality of an agent's preferences and beliefs, even if it is not assumed that there are independent, substantive standards for the critical assessment of individual ends. But this normative understanding of maximizing rationality is tenable only if it is at least conceivable that individual agents might occasionally fail to comply with its requirements – an 'ought' that it is not so much as possible to flout is not really an 'ought' at all. Proponents of the maximizing approach need to be attentive to the latent tension between the empirical and the normative aspirations of their theory, for maximizing rationality cannot claim both perfect empirical adequacy and normative authority for practical deliberation.

Assuming this tension can be resolved, further questions arise about the plausibility of the normative requirement to maximize expected utility. Doubts have been raised, for instance, in regard to the assumption that it is necessarily irrational to fail to select that action that would be optimal, relative to one's preferences and beliefs. Perfectly rational agents often seem to be content with states of affairs that are 'good enough,' from the perspective of their aims and desires, even when they are aware of alternatives that promise a higher return; they 'satisfice,' rather than seeking to maximize the value of the outcomes that they bring about (Slote, 1989). They also treat their past intentions and plans as fixed constraints on their decision-making, rather than attempting to maximize subjective utility anew in every situation they confront (Bratman, 1987). Some contend that maximizing rationality is flexible enough that it can accommodate alleged counterexamples of these kinds (Pettit, 1984). If not, however, there may be grounds for doubting that it represents a fundamental and uncontroversial norm for reasoning about action.

Specification, Expressive Rationality, and Moral Reasons

If maximizing rationality is not the unproblematic requirement of practical reasoning that it initially seemed to be, what are the alternatives to it? Consider the assumption that critical assessment of an agent's individual ends is off-limits. This apparently truistic assumption has been questioned by some philosophers, who point out that a great many of one's aims in life are rather inchoate; people want, for instance, to be successful in their careers, and loyal to their friends, without being entirely clear about what these ends require of them. To the extent one's ends are indefinite in this way, they will not provide satisfactory starting points for instrumental, maximizing, or even satisficing reflection. One will need to specify such ends more precisely before one can begin to think about which means they require one to pursue, or to generate from them a rank-ordering of possible outcomes. Here is a possible task for practical reasoning that does not fit neatly into the categories of *Zweckrationalität*, however broadly construed (Wiggins, 1987; Richardson, 1994).

Practical reflection about ends is not an easy or well-defined activity. There are no straightforward criteria for success in this kind of reflection, and it is not even clear when it has been brought to a satisfactory conclusion. These considerations are no doubt partially responsible for the assumption – especially widespread in the social sciences – that there is no reasoning about final ends. On the other hand, how is one supposed to clarify one's largest and most important ends, if not by reasoning about them in some way? Rather than exclude such reflection because it does not conform to a prior and possibly inappropriate paradigm of proper reasoning, perhaps the conception of practical reasoning should be expanded to make room for clarificatory reflection about the ends of action. To do so would be to acknowledge that practical reasoning can be both objective and subjective at the same time; by working out the meaning and implications of such commitments as loyalty or success, for instance, agents also help to get clear the values that define who they are (Taylor, 1985; *see* Hermeneutics).

A different point at which to question received models of practical reasoning is the theory of value to which they are committed. Maximizing and satisficing models alike seem committed to a consequentialist account of the relation of action to value: the thesis that value inheres ultimately in states of affairs, and that actions are to be judged rational to the extent they produce valuable states of affairs. This thesis seems at odds, however, with intuitive ways of thinking about value. It appears a distorted understanding of friendship, for instance, to say that what friends value fundamentally are states of affairs (involving, say, joint activities with the friend); what people value as friends are rather the concrete persons with whom they are befriended. This suggests a different way of conceptualizing the rationality of action. What makes actions rational, it has been claimed, is not the production of valuable states of affairs, but rather their success in expressing the attitudes that it is rational to adopt toward the true bearers of intrinsic value: people, animals, and things (Anderson, 1993). A supposed advantage of this approach is its ability to explain the rationality of behaviors that seem intuitively sensible, but that are hard to fit into the consequentialist scheme (such as commitments deriving from one's past involvement in an activity or project, which can look like an irrational weighing of 'sunk costs' to the consequentialist; compare Nozick, 1993).

Morality provides an especially fertile source of examples and problems for the theory of practical reasoning. One of the defining questions of moral philosophy is the question of the rational authority of moral norms: to what extent, and under what conditions, are people rationally required to comply with the demands of conventional morality? Reflection on this question has produced some of the most far-reaching and illuminating philosophical work on the nature of practical reasoning. Two divergent tendencies within this body of work should be singled out. Some approaches to

moral reasoning proceed by relating it to patterns of reflection familiar from other, non-moral domains, particularly the maximizing patterns canvassed in Section Instrumental and Maximizing Rationality. Thus it has been argued that, though morality imposes constraints on the direct pursuit of individual utility, these constraints can be justified in terms of the values expressed by ordinary economic rationality; a strategy of constrained maximization is recommended on grounds of enlightened self-interest, and this in turn accounts for the authority of moral norms to govern the practical reflection of individuals (Gauthier, 1986). Other philosophers have sought to make sense of morality as a source of rational norms by assimilating it more directly to the maximizing conception. For instance, proponents of *consequentialism* as an ethical theory – the theory that agents are morally required to maximize the good, impartially conceived – consider it an advantage of this account that it represents moral requirements in terms of the maximizing conception of rationality familiar from other contexts (Harsanyi, 1982; *see* Consequentialism Including Utilitarianism; Economics and Ethics).

A different approach stresses the discontinuities between moral and non-moral patterns of reasoning. According to this approach, morality is a source of constraints (such as prohibitions on murder and deception) that cannot be represented accurately within the framework of maximizing rationality (e.g., Scanlon, 1998). If this is correct, then those who wish to make sense of moral requirements, as norms that appropriately govern the reflection of individual agents, will need to expand their conception of the forms and possibilities of practical reasoning (*see* Social Work Ethics; Free Will and Action).

Abstract

Practice is a methodological and theoretical frame for investigating the relations between social individuals and the social and cultural milieux in which they live and work. 'Practice' is activity performed to produce an effect that is known or envisioned in advance by the performer. Practice is not the rote reproduction of social and cultural life. Praxis, rather than practice, offers a new dimension by examining how individuals are socialized into the roles and practices of their environment but also adapt the practices they have learned to the situations they confront. Such a perspective recognizes social and cultural change. Practice theory enables a dynamic and complex analysis of multiple social and cultural situations.

Introduction

Practice is a methodological and theoretical frame for investigating the relations between social individuals and the social and cultural milieux in which they are born, live, and work. It examines the actions and interactions that people engage in and how these activities produce results in the social world while simultaneously engendering the skills and subjectivity of the actor. The cumulative effect of these outcomes becomes the ongoing manifestations of what anthropologists and sociologists call social structure and culture.

For years, anthropology and anthropologists have studied the social activities comprising the minutiae of everyday life, as Malinowski has said, in order to abstract the principles of social organization, cultural beliefs and ideas, and the roles and statuses of community participants. The importance of such observations has never really been questioned, but the importance of the phenomena that were being observed was not always appreciated in its fullest dimensions. Anthropologists engaged in trying to understand not just the forms of culture and society but also the processes that produce and maintain them have looked at all manners of social and cultural phenomena to investigate these processes. These diverse activities have been credited with transforming individuals into social actors and binding these actors into social networks.

A theory of practice goes beyond observation and description of the activities that people perform, both daily and on special occasions, to look at "the integration of social organization, social action, and the production of meaning – the ways in which social processes are turned by practical activity into cultural forms and in turn inform the improvisation of social practices" (Calhoun and Sennett, 2007: p. 5). Thus, practice investigates how people's behavioral practices constitute productive processes that simultaneously and dialectically produce both the actors and the social and cultural networks in which they act. This intertwined realm includes construction and enrichment of both the individual aspects of motivation and desire, and the social complements of those features such as social values and cultural desires. In this way, practice theory seeks to overcome the mind–body dichotomy as well as the individual–collective divide. In both instances, the divides are both mediated and joined by their cocreation through ongoing activity.

'Practice' is activity performed in order to produce an effect known or envisioned in advance by the performer. The performance of the action in question serves reflexively as the objectification of this intention. In other words, the proper performance of the activity is the purpose, as for example in practicing the playing of a musical instrument. Such an act may be conceived as serving to improve one's instrumental technique or one's ability to perform more perfectly a particular piece of music with the instrument in question. Such practice has a dual effect. The performance of the act in the prescribed manner is essential to its purpose, but each enactment reflexively changes the way the musician performs the piece in an embodied and subjective way. At the same time, the rendition of the piece is a phenomenon that stimulates new understanding, aspirations, and desires in both the actor and the potential audience.

Just as earlier anthropological studies focused on an enormous array of social phenomena, practice-oriented anthropology looks at widely disparate types of phenomena in which actors perform processes that place them in social and cultural situations and networks and affect the outcomes of events in the world. Contemporary theorists of practice theory in anthropology have applied the insights to an enormous variety of social and cultural phenomena spanning subjects such as gardening and socializing children (Fajans, 1997), weaving (Greenfield), investment banking (Ho), cooking (Sutton) cheese making (Paxson), chocolate making (Terrio), producing the state (Byrnes), and surviving poverty in Oaxaca, Mexico (Mahar).

This convergence of one theoretical application to such a wide variety of topics is not really surprising because anthropology has always investigated a plethora of subjects, and many theorists have argued that these approaches are generally applicable to a large array of phenomena. The study of the social and cultural dimensions of practice is therefore part of the genealogy of anthropology over more than a century. The theoretical implications of these newer studies, however, have provided an added dimension.

Bourdieu and the Theory of Practice

The flowering of interest in practice theory arose after the publication of Pierre Bourdieu's *Outline of a Theory of Practice* in 1972 (English translation, 1977). What made Bourdieu's project different was that he made practice part of a theoretical analysis rather than just a component of the observation and participation that previous anthropologists had engaged in. He sought to find regularities in people's behavior that could be described both as part of a statistical analysis and as phenomena that went beyond what was attributed to be either in people's heads or in the world outside. He saw practices as uniting what is customary and strategic, as well as what is routinized and improvisatory. Individuals grow up in cultural settings where certain behaviors are taken for granted; new members learn them through implicit rather than explicit learning. Such activities are undertaken in (relatively) unconscious ways and are understood as the necessary foundations of social life. Bourdieu calls such routinized and unquestioned behavior and beliefs 'doxa.' Doxa is by definition unquestioned. What turns doxa into either orthodoxy or heterodoxy is the comparison of one implicit habitus with another. Bourdieu does not have a means of introducing change – even small adaptive change – into his notion of habitus. However, he believed such activities have to be understood in a temporal framework, taking into account variations in performance over seasons, life cycles, and changing social situations (Jenkins, 1992: p. 68). Bourdieu looks at patterns and practices over time to see how some aspects of the habitus vary in cyclical or oscillating patterns that differ from night to day, summer to winter, male to female, or old to young, or in many other ways. In these variations, he suggests, may be found the seeds of change and the grounds of adaptation to new practices.

Despite attributing greater importance to everyday activities as the building blocks of social and cultural life, practice theory often presupposes that actors perform their activities in relatively unconscious (or not wholly conscious) ways. This aspect of the theory is embedded in the idea of habitus. Other anthropologists have used the term 'habitus,' especially Mauss and Durkheim, but Bourdieu elaborated on the notion of habitus as a concept to surpass the mind–body dualism of received philosophy, and to act as a bridge between individual free will and socially determined structures of conformity. Habitus is a set of bodily practices, which Bourdieu calls "an acquired set of generative schemes objectively adjusted to the particular conditions in which it is constituted" (1977: p. 95). These schemes are a system of dispositions, which are both mental and bodily practices because they are in the heads of people but are also enactments of dispositions. When followed, these acts or practices have effects in the world that essentially produce a socially recognized and constructed world.

Bourdieu begs the question of how the central patterns of *habitus* are learned and, once learned, become motivated, so that the acting subject is led to repeat them in the same form. How this process of reproduction occurs remains unspecified, with terms like internalization, incorporation, and so on. But to move from statistically regular patterns to socially and culturally motivated ones requires an understanding of social meaning and social value. These qualities motivate actors to participate as social beings in cultural and social milieux and reciprocally make this participation meaningful. Action in this sense mediates between the subjective individual and the external social and cultural relations, structures, and activities that form the visible manifestation of both culture and social organization. Motivation in this conceptualization is not intrinsically linked to competition for status or dominance, but to the fulfillment of needs and desires that have culturally specific meanings. Bourdieu addresses these culturally specific values through his terms 'social capital' and 'symbolic capital,' but he is less clear on how subjects come to value and desire the particular capital of their social group. These values are established through repeated (although not necessarily identical) actions and interactions in complex social encounters. Since most activities are social, the practices most frequently examined by anthropologists construct the nexus of interpersonal social relations as they also produce an acting subject.

The significance of these social building activities is not always recognized. In much of Bourdieu's work, subjectivity, agency, consciousness, cultural symbolism, and meaning are left as abstract phenomena, primarily attributed as reflexive determinations of a self-reproducing social structure and the competition for relative distinction within it. The intricate specifics of the practices and actors in real situations are lost in the theoretical abstraction. This absence leaves the theory seeming more tautological than engaged. As Bourdieu says, doxa is the quasiperfect fit between the objective structures and internalized structures of agents that makes the structures in question appear natural and unquestioned.

Such a perspective cannot account for change. Although Bourdieu speaks of improvisation, he gives little evidence of how improvisation emerges or whether it can effect change. Others try to account for change between a subject and the external world by analyzing multiple embodied processes such as the senses that are both cognitive and bodily activities through which actors respond to their environment. In most cases, such cognitive and sensory responses cause minor alterations in social and behavioral relations, but these changes and adjustments open the possibility of more radical change and progressive evolution. The idea of social stasis is no longer an acceptable assumption, but neither is the idea that all things are possible. Cultures evolve and develop, and the expectations of behavior within them are socially valued and judged.

A More Inclusive Theory

An interest in the relationship between human action and social transformation can be traced back quite a long way, certainly back to Marx and Weber. But since then, oscillations between overly structural and overly actor-focusing frameworks have dominated perspectives (Ortner, 1989: p. 15). Practice has too frequently been associated with the rote reproduction of social and cultural life through the dialectic of action as production. Praxis, rather than practice (Marx, 1947), offers a new dimension to this more mechanical model. Praxis examines the way that activity is not just externally directed but also simultaneously part of the production of the subjectivity and consciousness of the actor (as in the

musician practicing an instrument) as it manifests an effect in the external world as well. Contemporary theories attempt to add a variety of theoretical insights to this theory. In particular, to understand the ways that embodied practices are not just rote and repetitive actions, theorists look to two other theoretical schools: Soviet and Eastern European activity theory and Piagetian social psychology. These add dimension to the development of practice theory.

The theoretical side of practice 'theory' shows strong convergence with activity theory. Activity theory, developed in the former Soviet Union and other Eastern European nations, derives from Marx's notion of *praxis* (Vygotsky, 1962, 1978). The theory of praxis from which this theoretical school developed uses a different definition of praxis than that most commonly used in the United States and Western Europe (cf. Sahlins, 1981; Levi-Strauss, 1966).

Praxis in this derivation refers to the form of action that is built upon a dialectical interaction between a subject and an external phenomenon, object, person, or idea. In this view, action is prior to either the subject or the object, which are considered abstractly or separately (prior in every sense: epistemological, experiential, developmental, practical, historical, and theoretical). Each action is reflexive: in acting on the object, the subject reflexively acts upon itself, is acted upon, and is affected by the object. Thus, praxis is simultaneously subjective and objective, material and ideal. It involves a subjective purpose and an objective constraint. Praxis refers to processes that are objectively and materially existent but are also the expression of subjective needs, ideas, and purposes. It is neither solely subjective nor wholly objective; rather, it is cultural because it is symbolically mediated. This may mean that the forms of the subject or object are constituted as cultural categories, but they are also mediated by special symbolic language (e.g., language, money, or special forms of exchange). These symbolic forms of praxis are the basis of social consciousness and cultural forms.

The boundaries usually constructed around the concepts of subject and object, internal and external, and entity and action are in this context part of a continuous relationship in which each part produces and in turn is produced by the others. In this relationship, activity holds the determinative role. The activity mediates internal-subjective states and motivations and external outcomes and relationships.

This dialectal relationship is expressed in other ways by other theorists. In particular, Jean Piaget builds both a psychological and social theory on the notion of schema. A schema is the form of a relationship between an acting subject and a portion of an objective external domain. It is based on a subject recognizing stimuli such as touch, language, events, and social interactions and learning appropriate responses to such events. The process of receiving and recognizing these stimuli is what Piaget calls 'assimilation.' The actor responds to such experiences in evolving ways, learning a more and more acceptable pattern of response. Piaget calls this response 'accommodation.' The response is a learned behavior, but it is not an instinctive one. When stimuli change and internal responses vary, so does the reaction of the subject. In this way, schemas contain the capacity to change and adapt to new contexts and situations. The concept of activity is broken into several different components, condensed as action and reaction, in which each is part of a feedback relationship that is fluid and potentially changing. The relation as a whole is the schema, and the actors and actions form a constantly evolving dynamic interface.

Change in both this and other senses has been a problem for many social scientists to account for or explain. The more successfully they describe the relationship between actors and their sociocultural context, the more difficult it is to imagine change arising from within this dialectical system. Practice theorists such as Ortner confront the way that cultural schemas sustain a 'kind of durability' (1989: p. 61). For this reason, many social theories have fallen back on change as requiring external forces. Ortner and other practice theorists have tried to refute the necessity for such outside intervention, believing and illustrating how culturally constituted engagements have a way of 'escaping' those intentions (Ortner, 1989: p. 89). Thus social variability, which is ever present in such common forms as age, class, and gender as well as ritual and mythic framings of subjectivity and motivation, can, in the context of differential experiences, initiate change.

As Lave and others (Lave and Wenger, 1991) have shown and argued in discussions of learning in both formal and informal settings, people do not learn in isolation but in the context of relations with others, so learning is social and depends on the situated contexts in which it occurs. The context of participation in both learning and practicing skills and knowledge is one of both reproduction and potential creative production. Lave is paradoxically trying to create a theoretical conception of learning without engaging in a process of abstraction.

This paradox is a key to thinking about practice as a fundamentally different understanding of the world: one in which activity is both the content and the structure of the phenomenon and is both the evidence and the theory of which it consists. Lave and Wenger "shift the focus from the individual as learner to learning as participation in the social world, and from the concept of cognitive process to the more encompassing view of social practice" (Lave and Wenger, 1991: p. 43). Viewing learning in this social context evolves from the theories of the school of social psychology led by Vygotsky. Vygotsky developed an approach to learning that "is characterized by the distance between the problem-solving abilities exhibited by a learner working alone and that learner's problem-solving abilities when assisted or collaborating with more-experienced people" (Lave and Wenger, 1991: p. 48). They call this a 'scaffolding approach,' in which learning is not so much a process of internalization as a process of social transformation: "In contrast with learning as internalization, learning as increasing participation in communities of practice concerns the whole person acting in the world" (Lave and Wenger, 1991: p. 49). In contrast with other approaches, this perspective focuses on a "continually evolving, continuously renewed set of relations" (Lave and Wenger, 1991: p. 50). "Because of the contradictory nature of collective social practices, and because learning processes are part of the working out of these contradictions in practice, social reproduction implies the renewed construction of resolutions to underlying conflicts" (Lave and Wenger, 1991: p. 58).

Practice includes the activities that people perform on both a daily and occasional basis. However, the deeper study of practice goes beyond the mere acts of daily life to look at the motivations, desires, and values that actors hold in relation to their acts and the ways in which their performance further instills such beliefs and values.

As Calhoun and Sennett say, "As practice, culture is neither Bagehot's 'hard cake of custom' nor the realm of pure creativity idealized in notions of genius. It is made and remade in almost imperceptible small ways as well as occasional large bursts of innovation. As practice, culture is an achievement, not simply an environment" (Calhoun and Sennett, 2007: p. 7).

To attend to practice is indeed to attend to the ways in which human actions are embedded in social organization. Its effectiveness is made possible, as Bourdieu shows, partly by the internalization of social relationships and beliefs through experience. New actions are produced in structured improvisations, informed by intuitions about current social circumstances, habits and capabilities drawn from previous ones, and cultural schemas. Culture, in this sense, appears as an abstract system of norms or knowledge and also as implicit, often embodied understandings of how things work. Practice examines the nexus of individuals, social groups, communities, and institutions and cannot be fully understood by looking at one element in isolation. Even monolithic institutions are composites of the workers who enact the practices everyday.

Anthropologists must look at the ways that activity is embedded in social situations as well as how such activities also produce social situations and relations. One way to see such processes in their most evident manifestations is to look at the processes of acquiring skills and knowledge. Such contexts of learning span a vast array of activities, from gardening to weaving, and from cheese making to investment banking. Many studies emphasize that learning is a complex and dialectical process that involves a good deal more than just knowing the 'rules of the game.' Although Bourdieu is particularly interested in these relatively unconscious patterns of learning which are a part of habitus, many analysts feel that Bourdieu's concentration on unconscious practices ignores many of the important aspects of social life. Often, the process of acquiring these skills evolves from knowing how to follow a set of rules to being able to improvise to achieve an end even when steps have to be varied or eliminated in the process. Even more significant is the ability to read the environment to judge the next step in processes as different as chopping wood, making cheese, or making stock trades. As Piaget proposes, the subject assimilates information and experience through a series of life encounters and uses these experiences to construct a schema of appropriate actions and reactions. When put in a situation requiring response, the subject-actor uses these experiences to act appropriately and adjust his or her actions to the particularities of the situation. In this frame, individuals are socialized into the roles and practices of their environment and also adapt the practices they have learned to the situations they confront. Situated practice is the ability to adjust to new situations in ways appropriate not just to the end desired but also to the community at large (Lave). The other side of this adaptive ability is the skill to alter the situation to fit the actor's desired outcomes. In this way, the study of practice and activity offers a way to understand both how individuals come to fit the cultural models and expectations of a person and how factors such as age, gender, class, race, and ethnic modes of behavior modify these expectations. The sum of such activity perpetuates the structure of the community in which they live, but at the same time opens the possibility of (subtle) change and alteration that emerges from each instance of practice.

Bourdieu's focus is on the visible world of social practice, but more recent practice theorists have looked at the processes in less material realms, including the analysis of myth and history (Ortner, 1989) and finance (Ho, 2009). Others have examined the activities of petty bureaucrats as the building blocks in the construction of large state apparatuses (Byrnes). Ho uses Bourdieu's ideas of disposition and habitus to discuss the practices of investment banking culture and the ways that these, "plus ways of being, inclination, and predisposition of the body constitute a collective habitus and system of dispositions, which organize action, produce practices, and construct social structures and worlds" (Bourdieu in Ho, 2009: p. 11). In this context, the dispositions go beyond what earlier analysis investigated and examine the production of the subjectivity and habitus of investment bankers and how they perform the acts of being elite and powerful. Power gives them the sense that they can be risk takers. Cumulatively, these actions affect the larger industry culture.

As Ortner says, practice is an activity in a political sense and is linked to structure: "The structural questions here normally concern the 'internalization' (if one takes an actor-centered perspective) or 'reproduction' (if one takes a system-centered perspective) of structure through practice" (1989: p. 194).

Most practice theorists see these processes from the actor's point of view, but they are not rules in the conventional sense. As Bourdieu insists, these activities are conceptually bound patterns of action formulated from the actor's subjective point of view. If one takes a broader view, however, activities are parts of schemas that connect subjects with the objective world through activity. They are schemas as defined by Piaget (1962) and Fajans (1997).

This more 'bird's-eye' view also allows a temporal perspective. As Ortner says, "a theory of practice is a theory of history. It is a theory of how social beings with their diverse motives and diverse intentions make and transform the world in which they live. It is a theory that allows social and cultural analysts to put all their various methodological tools to work – ethnographic and historical research; structural, interpretive, and 'objectivist' analytical approaches – in ways that enhance and enrich the effectiveness of each" (1989: p. 193).

The Many Forms of Activity

To understand how anthropologists approach and use all of these tools in practice theory, one must examine the range of contexts and analyses that emanate from this theoretical perspective.

Fajans applies practice theory to uncover the underlying schema of the Baining of Papua New Guinea. She looks at the many aspects of Baining social life that are premised on an overarching set of values that the Baining achieve through a range of activities. Although appearing as disparate activities,

these different processes produce similarly valued ends. These activities include the transformations that human work produces in such diverse contexts as swidden gardening, feeding children, and constructing dance masks. Each of these activities is, for them, a transformative process in which natural entities, the forest, an unsocialized child, and unconnected leaves and bark are transformed into a social product that itself has productive capacities (Fajans, 1997).

In a quite different social context, Paxson (2012) describes the many techniques of making artisanal cheese. Although the basic steps of cheese making are routinized, the cheese makers she describes are constantly monitoring and reading the environment of the cheese room and the progress of the transformation from milk to cheese. Paxson follows the cheese makers' own descriptions of their activity, which they understand as both art and science. These producers are constantly reading the environment of their dairy and adjusting their activities according to temperature, humidity, the speed of curd formation, and so on. The cheese makers know the process but adjust the minutiae of the activity in accordance with the actual development of the curd, which they come to know both cognitively and bodily. Each day might be subtly different from the day before and after. They have a feel for the game, but they are open to shifts in practice. Sometimes, their acts produce something quite new and different. This can be an exciting new creation or a problematic failure, but either way they are modifying and changing the practice in a fairly continuous way. This understanding of practice instantiates the notion of skill proposed by Ingold (1983) in which skill is performed as an extension of the mind and body in interaction with an environment that changes in response to the actions of the subject. The art and science of cheese making comprise a good example of practice as habituated by adaptive and nonrote activity as described here.

In a related example, Sutton (2012: p. 302) studies how people learn to cook. Cooking in much of the world is an activity that occurs frequently, in close proximity to many other activities, and in spaces frequented by members of a household. In such contexts, it is hard to separate a context in which learning to cook is separate from other social engagements and activities. In this respect, cooking forms part of the habitus, an accepted and relatively unconscious aspect of day-to-day life. Although this is an activity in which individuals are immersed from early childhood, young members of the household are only gradually instilled with the knowledge not only to understand what others are doing but also to do it themselves. In many contexts, the actual practice of the art of cooking may be restricted to particular genders, classes, or professions. Such learning may be subtle, with the assignment of progressively harder chores, and it may appear effortless, but it may also occur with specific instruction and potential criticism when not done properly. Much of this learning and teaching is a form of apprenticeship, learning from one who knows the skills to be acquired. Apprenticeship can range from quasiformal instruction in a task to much more subtle acquisition of a skill through long-term proximity. As Lave and Wenger (1991) describe, learning in a social setting often stimulates students to achieve greater mastery than they would on their own. Much traditional learning is social in this way. In cooking, however, as in cheese making, the end product of the activity must have certain characteristics. Learning to cook requires knowing how particular foods or dishes should look, smell, and taste (Sutton, 2012). Just performing the skills of cooking may not produce the desired ends.

Cooking shares with more formal activities the need to learn certain basic skills and procedures, but it also requires the ability to improvise and adapt. In many apprenticeship situations, however, the standard requires the novice to first learn the skill as practiced by the more authoritative members of the group, and only after proving that ability would improvisation be permitted. Terrio (2000) describes the rigorous requirements to become a chocolatier in France, but once initiated into the guild, practitioners vie to outdo their peers in their production. Again, the presence of a community stimulates performance. Even in this case, however, there are constraints. Actors have to conform to certain cultural and social criteria that define authentic and proper behavior.

Practice theory has also been used to examine the ways that urban squatters adjust to and make sense of their lives in new settings, that is, how they reconfigure the relations between structures and habitus. Anthropologist Cheleen Mahar examines these adaptations by looking at how migrants use memory and imagination to interpret their social conditions and subjective experience. Because memories are both individual and collective, the uses they make of memory are both subjective and social. In addition, the stories they tell and the events they experience are perceived through a process that is both social and corporeal (Mahar, 2010: p. 4).

Recently, anthropologists have looked at activity in more abstract terms. Analyses of social actors who perform various tasks like stock transactions and petty bureaucratic jobs offer a new understanding of the ways that day-to-day activities produce larger social formations and structures that appear external to the actions of individuals but are dialectically imbricated in their actions. Byrnes has elucidated how regional representatives of the state bureaucracy for monitoring manufacturing and industry embody and enact the state in their encounters with local workers and businesspeople. In these instances, the seemingly small and somewhat insignificant interactions nonetheless instantiate the relations of power and authority in the region. The monolithic state is continuously produced through such mundane interactions.

Similarly, Ho (2009) analyzes the Wall Street banking industry through the practices and habitus of its investment bankers. These employees enact a particular habitus of hard work, knowledgeable understanding, and intelligent risk taking that, when combined, defines a set of values that distinguish the banking sector in which they work. They simultaneously perform these roles and are motivated to embody these qualities in order to appear potent in their jobs.

Conclusion

Practice is both a form of action and a means of analysis; it encompasses both description and theory. Attending to practice means examining the coproduction of individual and sociocultural domains through multiple acts of speech,

performance, kinship, and so on. In each of these, the activity is a manifestation of an intention or desire, an effect in social relations, and a means of transforming one's relation within the intersubjective world in which one participates. Activity in this sense is a productive behavior, an expression of a relationship, and a moment in an ongoing dynamic of production. Practice theory enables a dynamic and complex analysis of multiple social and cultural situations.

Pragmatic Disorders

Brigitte Stemmer, Université de Montréal, Montreal, QC, Canada; Brock University, St. Catherines, ON, Canada; and CRIUGM, Chemin Queen Mary, Montreal, QC, Canada

Published by Elsevier Ltd.

Abstract

Not being able to appropriately tell a story, have a conversation with someone, make a request, and understand metaphors, ironic statements or jokes despite an unimpaired language system are examples of pragmatic disorders. They can occur in childhood as well as in adulthood when the brain is afflicted by a stroke or some other injury or disease process, and can be devastating and affect our psychosocial well-being, mental health, and occupational success. This contribution addresses questions such as what is linguistic pragmatics, when do pragmatics disorders occur, and how are they explained.

Introduction

The impact of disorders of pragmatics may be at least as devastating as disorders with the structural use of language. Both disorders can influence a person's mental health status, psychosocial well-being, and occupational status and success. Unlike structural and semantic disorders of language, however, disorders of pragmatics are usually less obvious and more difficult to recognize as a handicap (for a discussion see Cummings, 2011). For a long time, the description and evaluation of language disorders focused on phonetic, morphological, syntactic, and semantic aspects of language. This, however, does not adequately explain the richness of meanings that arise in the complex interaction between people. Consider the following question, "What do Barack Obama, Angela Merkel, and Marilyn Monroe have in common?" You may not know the answer, neither do I, but by now you probably guessed that the utterance is the beginning of a joke and whatever the answer, it will play on some characteristics of these people, what you know about them or situations surrounding them. And you did not make this inference solely based on the words strung together by some grammatical rules but additionally on what was not said, or your pragmatic knowledge. The way language is used and interpreted while taking into consideration the characteristics of the interlocutors and the effects of contextual, situational, and social variables is subsumed under the notion of linguistic pragmatics. Linguistic pragmatics refers to the way language is used in interaction for the purpose of communication. It is the impairment of this aspect of language that is the focus of this article. To understand what these impairments entail, it is useful to discuss in more detail linguistic pragmatics first.

Language as Social Action

Looking at the way language is used rather than simply at the words and grammar is credited to philosophers such as Ludwig Wittgenstein, John Austin, John Searle, and H. Paul Grice. Work in this tradition summarized key features of language as social action and analytic frameworks were developed for understanding how language works. Discourse scholars later applied these analytic frameworks to sequences of text and talk in context. The classic pragmatic models – usually focusing on isolated utterances – were thus expanded and modified to incorporate influences from other approaches such as discourse pragmatics (for a summary see Blum-Kulka and Hamo, 2011).

An analytic framework that has been used frequently to detect pragmatic impairments is the one developed by Austin and Searle for speech acts (such as convincing or inviting someone, making a promise, complaining to someone, and so on) (Austin, 1962; Searle, 1975). What we actually 'say', that is the linguistic means we use to utter speech acts, may be different from the content we intend to communicate. For example, an utterance such as "I'll go ice climbing next weekend" may be an invitation to someone to join in or information that I won't be home next weekend. "It's cold in here" may be information about the temperature in the room, or it may be an indirect request for closing the window. Under normal circumstances, we are pretty good at understanding what the utterance is supposed to mean – although misunderstandings may occur. How is this possible? One influential theory suggests that we perform reasoning steps to recognize what a speaker wants to imply or communicate (so-called implicatures); (Grice, 1975, 1978). We do so by assuming cooperation between the interlocutors, which is guided by following a set of maxims such as the maxim of quality (truthfulness: do not say that which you believe to be false or that for which you lack adequate evidence), the maxim of quantity (informativeness: make your contribution as informative as is required, but do not contribute more information than is required), the maxim of relation (relevance: make your contribution relevant to the exchange), and the maxim of manner (clarity: be brief and orderly, avoid ambiguity and obscurity of expression).

Although Grice's theory had and still has an immense influence in pragmatic studies, it has been challenged on theoretical and empirical grounds. One criticism concerns the assumption that the comprehension process is guided by predictable expectations that are derived from principles and maxims. Some researchers have argued that when people communicate they always have something in mind that is relevant to them and thus the maxim of relevance always applies (and similar arguments have been advanced for the other maxims). What is important is that the message is 'relevant', that it is meaningful and makes sense to the speaker and hearer in a 'mutual cognitive environment' (Sperber and Wilson, 1988). In their relevance theory Sperber and Wilson

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54027-6

(1988, 2007) thus subsumed the Gricean maxims as one supermaxim called 'Relevance.' At the same time, they introduced a psychological component to the verbal comprehension process.

Another criticism is based on the argument that pragmatics is not only implicated in what is communicated but also in what is said. During normal language understanding different aspects of pragmatic knowledge are accessed such as deep, default, or stereotypical background knowledge that provides an interpretation of what speakers say (primary pragmatic knowledge) (Gibbs, 1999; Recanati, 1993). Another aspect involves specific, local contextual factors that guide the interpretation of what speakers implicate or communicate (secondary pragmatic knowledge). It is, however, not clear what criteria to use to determine what counts as primary and what as secondary pragmatic knowledge and the usefulness of distinguishing primary and secondary pragmatic knowledge has been questioned. Some pragmatic knowledge might be more salient than other depending on the knowledge and experience we have accumulated during our life time, the knowledge and experience that is activated, and the affective states we are in. In fact, it has been suggested that it is the degree of salience rather than inferences made on the basis of the linguistic or nonlinguistic context that determines the meaning of an expression (for a summary of the graded salience hypothesis see Giora, 2003).

The Notion of Pragmatic Disorders

Although there is currently no agreement on how we arrive at the proper interpretation of an utterance or a discourse, there is agreement that this ability can be impaired in children as well as in adults. Already in 1983, in their attempt to classify developmental language disorders, Rapin and Allen (1983) described a syndrome of language impairment, which they termed the 'semantic-pragmatic deficit syndrome.' Children suffering from this syndrome were described as being overly verbose, having poor turn-taking skills in conversations, poor discourse and narrative skills, and having problems with initiating, maintaining, and terminating discourse topics. The term was later modified to 'semantic-pragmatic disorder' by Bishop and Rosenbloom (1987). A debate ensued around the validity of using the term as a diagnostic label for developmental language disorders. Some researchers (e.g., Aarons and Gittens, 1993) argued that the children described with these disorders also had cognitive deficits typical for autism and that 'semantic-pragmatic disorders' was a disorder belonging to the autistic spectrum. This was supported by reports that did not find differences between semantic-pragmatic syndromes or disorders and autism (Bishop, 1989; Boucher, 1998; Gagnon et al., 1997). Subsequently, semantic-pragmatic disorders were mostly viewed as part of the autistic spectrum rather than as a developmental language disorder. The modern day successor of the term semantic-pragmatic disorders is pragmatic language impairment (PLI), pragmatic disorders, or clinical pragmatics with the latter term sometimes viewed as a subcategory of pragmatic disorders.

Theorists and clinicians frequently distinguish between primary and secondary pragmatic disorders. Whereas primary pragmatic disorders describe deficiencies that are not a consequence of linguistic problems, secondary pragmatic disorders describe an individual who suffers from deficiencies of structural language, which affects his or her pragmatic competence. For example a person who is not able to produce a grammatically correct sentence (**Drive home*) may be unable to appropriately produce a request (*Could you give me a lift home?*), open or take turns in a conversation (*I would like to pick-up your previous argument; May I interrupt you here?*), produce narratives, and so on. In such cases, we say that the pragmatic impairment is secondary to a deficient linguistic structure. This is different from someone whose language is intact but who does not know or understand how to appropriately open a conversation or to produce speech acts according to the context and situation. For example, saying to a friend "My car broke down this morning. Give me a lift home tonight, ok?" would be appropriate if addressed to a friend but not to a colleague at work where it might be more appropriate to say something like "My car broke down this morning. It would be really nice if you could give me a lift home. It's not much out of your way." The distinction between primary and secondary pragmatic disorders is, however, problematic. Many individuals that show pragmatic inappropriateness also exhibit cognitive problems (such as attention, memory, or executive functions) and it is not always clear what was first, the chicken (pragmatic disorder) or the egg (cognitive problems).

Pragmatic Disorders in Children and Adults

Pragmatic disorders have been described in children during development and in adults subsequent to some type of brain injury or brain abnormality. Although studies of pragmatic impairments emerged more than 30 years ago, many issues are still controversial or require clarification. An important and still controversial question is whether pragmatic disorders exist as an independent entity or whether they are associated with some specific disease or subsequent to mental or cognitive impairments. In addition, if structural language problems exist, it is not always easy to determine to what degree these problems influence or lead to pragmatic deficiencies. Another issue concerns the assessment of pragmatic impairments. On the positive side, there is agreement that not only structural aspects of language but also pragmatic skills need to be evaluated and many assessment instruments that target classic language skills nowadays also include pragmatic components. On the negative side, assessment instruments targeting pragmatic disorders are frequently not standardized, lack real-life application (ecological validity), rely primarily on reports by friends or family members, lack cultural adaptation, or require too much time (or expertise) to make them clinically useful. Scientific studies of pragmatic disorders often focus on specific aspects of pragmatic disorders, on specific patient groups and use different analytical frameworks. All this makes it difficult to establish whether pragmatic profiles exist and if so whether they are common or distinct between patient populations and within a patient group.

Developmental Pragmatic Disorders

When evaluating pragmatic impairments in children, the developmental process also needs to be considered. It may not always be possible to determine whether pragmatic deficiencies are due to a language system that is not yet fully developed or due to immature pragmatic skills, or whether we are dealing with 'pure' pragmatic disorders (assuming they exist). Another question that arises is whether a specific disease (such as autistic spectrum disorders, ASDs) is characterized by features that overlap with pragmatic skills such as social aspects of communication.

Autism Spectrum Disorders (ASD)

Autism spectrum disorders (ASDs) are characterized by impairments in the domains of communication and social skills, and by restricted, repetitive patterns of behavior, interests, or activities. Pragmatic impairments are considered a salient feature of these disorders. Studies have demonstrated deficiencies with making inferences and comprehending speech acts and figurative language such as metaphor and irony, evaluating humor, or detecting violations of or adhering to Grice's maxims. Individuals with ASD do not make use of context to appropriately explain nonliteral utterances such as sarcasm and jokes. They also show abnormalities in conversational behavior such as talking either too much or too little and having problems with taking turns. They also fail to follow politeness rules and make irrelevant remarks. The most commonly used explanations for these deficiencies are the theory of mind (ToM) and the central coherence weaknesses hypothesis, or both. Weak central coherence refers to a tendency to interpret utterances in isolation without integrating information from many sources. ToM weaknesses refer to difficulties with inferring the goals, emotions, and beliefs of other people on the basis of their mental states (for summaries see Cummings, 2009; Loukusa and Moilanen, 2009; Tager-Flusberg and Caronna, 2007). However, not all researchers adhere to these views. It has been argued that the central coherence hypothesis does not distinguish between contextual processing and processing at a local level (such as within a text). These are considered independent abilities and individuals with ASD do not have problems with processing at a local level (Martin and McDonald, 2003). Others have questioned the validity of ToM as an explanation for pragmatic difficulties of individuals with ASD. The argument is that most of these individuals also have executive-function problems that require planning, flexibility, and working memory abilities, and these abilities are related to performance of ToM tasks. Further, not all individuals with ASD show problems with ToM tasks. In addition, different brain regions seem to be activated in individuals with ASD compared to healthy individuals (for a summary see Tager-Flusberg and Caronna, 2007).

Specific Language Impairment (SLI)

Specific language impairment (SLI) is a developmental language disorder of unknown etiology. These children exhibit 'specific' language problems, and it was traditionally assumed that motor, sensory, and nonverbal intellectual abilities are unimpaired. However, studies showing that SLI children frequently demonstrate reduced processing speed, working memory, and attention shifting impairments have questioned the traditional view. Frequently described language problems are morphosyntactic errors (e.g., past tense marking) and lexical semantic errors alongside a large range of other verbal difficulties. Traditionally, it was assumed that SLI children are unimpaired in pragmatic skills or, if they occurred, they were viewed as secondary to the structural language problems. Some authors have, however, argued that a subset of the SLI population show pragmatic impairments that cannot be explained by their structural language problems (for a summary see Cummings, 2009). Among the pragmatic deficiencies described are inappropriate responses in conversations, decreased ability to use context to comprehend implied meanings, and decreased performance on inferential comprehension tasks (for summaries see Bishop, 2000; Cummings, 2009, 2010).

Other Developmental Disorders

Whereas there is a large literature investigating pragmatic impairments in individuals with ASD and SLI, fewer studies have investigated pragmatic impairments in other developmental disorders. A diverse range of pragmatic impairments that are difficult to reconcile have been described in children with genetic disorders such Down's syndrome (47 chromosomes, XX), Klinefelter syndrome (47 chromosomes, XXY) Williams syndrome (spontaneous deletion of genetic material from chromosome 7), or fragile X syndrome. Pragmatic impairments have also been reported in about 70% of children with emotional and behavioral disorders (reviewed by Benner et al., 2002) and in children with ADHD (Cummings, 2013). Some studies have described pragmatic language impairment in children outside of any developmental disorder while others have raised doubts that pragmatic language impairment exists without autism (Boucher, 1998; Gagnon et al., 1997; Gibson et al., 2013).

DSM-5: Social (Pragmatic) Communication Disorder (SCD)

Before ending this section, a brief note on the new diagnostic category introduced in the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) is warranted. The DSM-5 published in 2013 (American Psychiatric Association, 2013) has added 'social (pragmatic) communication disorder' as a new diagnostic category to "ensure that the unique needs of affected individuals are met." ASD must be ruled out for SCD to be diagnosed. DSM-5 characterizes the disorder as follows:

> SCD is characterized by a persistent difficulty with verbal and nonverbal communication that cannot be explained by low cognitive ability. Symptoms include difficulty in the acquisition and use of spoken and written language as well as problems with inappropriate responses in conversation. The disorder limits effective communication, social relationships, academic achievement, or occupational performance. Symptoms must be present in early childhood even if they are not recognized until later when speech, language, or communication demands exceed abilities.

The new diagnostic category has raised much controversy and criticism. Some argue that SCD does not have reliability

or validity as a distinct category of neurodevelopmental disorder. It is argued that SCD does not exist as an independent entity but seems to be associated with other disorders such as autism, SLI, or ADHD (see previous discussion; for a summary see Norbury, 2013; Helen Tager-Flusberg, 2013). It has further been criticized that the currently available assessment instruments either lack standardization, which are not ecologically valid, or rely too much on parent or teacher report measures (Helen Tager-Flusberg, 2013). SCD is also prone to cultural bias or interpretation. It thus remains to be seen whether SCD as a new diagnostic category will survive DSM-5 updates.

Acquired Pragmatic Disorders

Pragmatic impairments can also occur outside the developmental phase such as when injuries to or disease of the brain occurs. Such acquired pragmatic disorders have been reported in patients after a stroke to the left or right hemisphere, in patients with traumatic brain injury (TBI), in patients with a tumor, or in patients with neurodegenerative disease (such as dementia or Parkinson's disease). Some of these patients may not show any structural or semantic language impairment and yet present with severe pragmatic impairments (for reviews of pragmatic disorders in various patient populations see Cummings, 2009, 2013; Stemmer, 2008b).

Cerebrovascular Disease: Right Hemisphere Damage (RHD) and Left Hemisphere Damage (LHD)

The most common reason for right- or left hemisphere damage is an interruption of blood supply to the brain such as a blood clot in an artery (ischemic stroke) or a rupture of a blood vessel (hemorrhagic stroke). A stroke damaging neural circuits in regions of the left frontal or temporal lobes of the brain is frequently associated with language production or comprehension problems such as Broca's or Wernicke's aphasia. Damage to neural circuits in the right hemisphere of the brain have been associated with disorders of pragmatics including affective prosody, aspects of discourse (e.g., conversational and narrative style, coherence, speech acts) or figurative language (e.g., metaphor, irony, joke). Consider the transcript of a right hemisphere damaged (RHD) patient's attempt to summarize a story about a plane crash that had been read to him (see **example 1**). Although his linguistic skills are unimpaired and neuropsychological testing did not reveal attention or memory problems, it is obvious that he diverges from the main story and introduces new elements irrelevant to the summary and which were in fact not in the story. Some (but certainly not all) RHD patients display a somewhat odd narrative style, which has been described as embellishing, rambling, tangential, noninformative, irrelevant to the central topic and confabulatory. They show problems with discourse organization reflected in story structure, cohesion and logical coherence difficulties. They may jump from topic to topic leaving the listener with gaps of information, miss the overall point of a conversation or show difficulties extracting the relevant themes of a story. Besides these discourse problems, RHD patients have also demonstrated problems with using prosody to interpret the emotional content of discourse.

Example 1

(^ indicates a pause)

Patient: Well ^ yes ^ Laura was on her way to ^^^ hm ^^ I forgot ^^^ anyway she was on a plane and then there was a terrible noise and the plane kept falling and falling and it must have really been scary ^^^ yeah ^^^ I remember there was this plane crash last year in the US ^^^ I forgot exactly but many people died although some survived ^^ it's a real miracle ^^ you know ^^ can you imagine being in a plane that crashes ^ I mean ^ hm ^ yeah ^ actually I read somewhere compared to car accidents plane crashes are very very rare ^^^ yeah ^^^ ^^^

Therapist: ok ^^ you said that Laura was on a plane and the plane kept falling.

Patient: hmm ^^ oh yes ^^ right ^^ and there was this thunderstorm and the tent was on this cliff with people screaming ^^^ being in a tent when it rains is no fun …

Other pragmatic difficulties include problems at the level of integrating various pieces of information to build new situation or mental models. In Example 1, the patient was able to make global inferences. Although it was never explicitly mentioned in the text, the patient inferred that the plane had crashed, that there was a thunderstorm and that Laura was in a tent. The text explicitly mentioned that the person in the tent was having a dream. Nevertheless, the patient was not able to 'combine' the pieces of information to come up with the correct story in which Laura was in a tent during a thunderstorm and dreaming of a plane crash.

Similar to narratives, using and understanding figurative or nonliteral language (such as nonconventional indirect requests) requires the ability to draw inferences and integrate a wide range of information sources. A large literature has documented the difficulties of RHD patients with figurative and nonliteral language that requires such integration processes. For example, an RHD patient might associate the metaphor "He had a heavy heart" with a picture of a person stumbling under the burden of carrying a large heart. But he may not be able to draw on his experience and knowledge of the world and integrate these pieces of information to come up with the right interpretation.

(For summaries of pragmatic disorders in RHD patients see, for example, Joanette and Brownell, 1990; Champagne-Lavau et al., 2006; Cummings, 2009, 2013; Stemmer, 1999, 2008a,b; Winner et al., 1998).

Aphasia is a language disorder usually provoked by a left hemisphere lesion, most frequently (but not exclusively) caused by a stroke. Like patients with RHD, aphasic patients are a heterogeneous group and, based on their linguistic performance, several aphasic syndromes have been described. Depending on the aphasic syndrome displayed, these patients are differentially impaired in their ability to comprehend and/or produce language. Studying pragmatic abilities in these patients can thus be challenging and it is difficult to determine whether the pragmatic difficulties are due to the language impairment or if these are discourse problems per se. A lack of initiating discourse and topic changes, a reduced query production or a reduced variety in the use of types of speech acts, less informative discourse and less specificity, and

accuracy of the message have been described in aphasic patients. Most researchers attribute pragmatic difficulties in LHD patients to their linguistic impairment. There are, however, a few studies that seem to suggest that these difficulties may be independent of linguistic impairment. The issue is currently unresolved.

Traumatic Brain Injury (TBI)

Car and sport accidents, violent crimes, and so on can cause injury to the head and lead to what is called TBI. Patients suffering from TBI are a particularly heterogeneous group because a trauma can affect all parts of the brain and frequently more than one lesion site is involved (and thus various brain networks affected). This makes it very difficult to compare research findings and arrive at generalized conclusions. Many TBI patients show normal lexical and grammatical skills. Some TBI patients, especially those with damage to the frontal lobes of the brain, exhibit pragmatic impairments similar to patients with right hemisphere lesions such as in formulating nonconventional indirect requests despite preserved sensitivity to social factors. TBI patients with frontal lobe involvement frequently display impairments of executive functions, that is a constellation of disorders including difficulties with problem solving and mental flexibility, a failure to abstract, perseverative behavior, and a loss of control and monitoring functions. Executive impairments can severely interfere with narrative or conversational discourse production. TBI patients have been reported to exhibit poor topic management and to produce disorganized, repetitive, and over- or underdetailed discourse. Other pragmatic impairments documented in TBI patients are difficulties with using or detecting figurative or nonliteral language such as the use of nonconventional indirect requests or sarcasm and deficiencies in using politeness markers.

Neurodegenerative Disorders

Neurodegenerative disorders include various types of dementia but also patients with Parkinson's disease, Huntington's disease, multiple sclerosis and so on. Studies of patients with Alzheimer's disease have demonstrated difficulties with opening a conversation, comprehension of figurative language, and ToM tasks. Alzheimer patients have also demonstrated lexical and syntactic impairment, which makes it difficult to judge to what degree the linguistic impairment influenced the pragmatic deficiencies. Patients with frontotemporal dementia exhibited problems with organizing discourse and ToM tasks and showed poor performance in moral reasoning, emotion processing, and showing empathy. Patients with Parkinson's disease have been reported to show poor performance with the comprehension of figurative language (irony, metaphor) and speech acts as well as with turn taking in conversations.

Psychiatric Disease

Among patients with a psychiatric disease, schizophrenia is the one that has been most frequently investigated in terms of pragmatic disorders. Impairment in social functioning has been a hallmark of schizophrenia and a series of studies has shown that schizophrenia patients display problems with ToM tasks. At the discourse level, patients with schizophrenia demonstrate difficulties adhering to a topic, distinguishing relevant from nonrelevant content and have difficulties with taking turns in conversation (for a summary see Meilijson et al., 2004). Schizophrenia patients also exhibit difficulties with interpreting nonconventional indirect requests (such as "It is raining outside" intended to mean "Give me a lift home") and figurative language such as metaphors, irony, idioms, or jokes.

Explaining Pragmatic Disorders

The previous discussion has shown that pragmatic language disorders can be identified in patient populations that are rather heterogeneous. Many of the pragmatic 'symptoms' overlap and do not seem to be specific for any patient population. What has emerged from lesion studies is that pragmatic disorders can occur independently of language disorders such as in RHD patients and that language disorders may lead to pragmatic deficiencies. These observations are supported by neuroimaging studies indicating that communicative abilities (including pragmatic abilities) and language abilities rely on different cortical systems (for a review see Willems et al., 2010).

Several suggestions to explain or find the underlying cause for pragmatic deficiencies have been made. Prominent ones are the ToM hypothesis, the inferencing hypothesis and the mental model hypothesis (for a summary and discussion see Martin and McDonald, 2003; Stemmer and Joanette, 1998; Stemmer, 2008a). Consider the ToM hypothesis: If you are not able to infer and thus represent in your own mind another person's mental state (such as her hopes, beliefs, beliefs about beliefs, moods, desires, intentions), then you will not be able to employ such representations to interpret, predict, and judge the utterances and behavior of the other person. The ToM hypothesis is closely related to the inferencing hypothesis in that the ability to make inferences about other people's mental states is central. The inferencing hypothesis suggests that the pragmatic impairments observed are due to difficulties generating inferences at local and global levels such as making inferences from a text you read in the newspaper, from a statement made by your friend, or from the position of cars involved in an accident. Testing this hypothesis has, however, produced diverging results possibly due to a lack of properly defining what was meant by inferencing, a neglect in distinguishing between different types of inferencing and also a lack of a theoretical framework such as inference generation models. The mental model hypothesis has been viewed as an orverarching theory encompassing the ToM and inferencing hypothesis. In this view, we use the information available to us to construct mental models (or modify or integrate them), in order to understand, explain, and predict phenomena of the environment, and to act accordingly. It has, for example, been suggested that the problems observed in the RHD patient in example 1 and in other patients with pragmatic problems was due to an inefficiency in manipulating or updating mental models they had constructed. Although the mental model hypothesis seems to account best for many of the pragmatic impairments described, none of the hypotheses discussed here is able to fully explain the many different facets of pragmatic impairments. Reasons may be that pragmatic impairments are a conglomerate of very diverse 'symptoms' that may have

different and/or multiple causes that are difficult to capture by one theory.

There is some empirical support for the claim that pragmatic disorders may occur without other cognitive systems (such as executive functions including attention and working memory; monitoring and control systems, language) or emotional components being impaired. Some doubt has, however, been raised whether such cases indeed exist as the evaluations used in the studies to exclude cognitive impairments may not have been sufficiently exhaustive or the instruments used may not have been specific enough to capture the impairment. This issue is still controversial.

Pragmatic Disorders and the Brain

Numerous studies have associated the frontal lobes of the brain with pragmatic functions. The frontal lobes cover a large area of the brain, are subdivided into several anatomical subregions and have rich connections to other parts of the brain. It is important to note that the frontal lobes are not a unitary system as they are implicated in a variety of functions such as language production (Broca's region), executive, inhibiting, and control mechanisms (see Figure 1). The frontal lobes also play a role in self-awareness and consciousness, social and personality development and various memory functions. It is thus not surprising that damage to the frontal lobes and the prefrontal cortex (PFC) in particular can lead to pragmatic impairments as has been described in various patient populations. It is also not surprising that – due to the functional fractionation of the frontal system and its rich relationship to other neural networks in the brain – damage to different frontal lobe systems and their interconnections may affect pragmatic performance in different ways. Most clinical studies have not considered the functional fractionation of the frontal lobe system in a systematic way nor investigated its effect on different facets of pragmatic behavior. Another issue that needs to be solved is the observation that patients with lesions outside the frontal lobes have also shown pragmatic impairments.

(For summaries see Ferstl et al., 2008; Ferstl, 2010; Stemmer, 2008a, 2008b, 2013) (*see* Lateralization of Language as Demonstrated by Brain Imaging Procedures).

Considering the difficulties of investigating clinical populations, the hope has been that modern neuroimaging techniques (such as functional magnetic resonance imaging (fMRI), event-related potentials (ERPs) and so forth) would shed light on these issues as these techniques can also be used with healthy populations and thus eliminate the problems inherent in patient studies. Neuroimaging studies investigating discourse and figurative language in healthy populations only partially confirm the findings of behavioral studies with patient populations. Although early behavioral studies implicated the right hemisphere in high-level discourse and nonliteral/figurative language studies, later behavioral studies were more controversial on these issues. There is general agreement from neuroimaging studies that figurative and nonliteral language processing does not necessarily involve the right hemisphere but does so at times. The exact circumstances under which the right hemisphere is implicated still need further clarification. Structural discourse as well as figurative and nonliteral

Figure 1 The bottom hemisphere shows the lateral view of the brain (i.e., looking at the brain from the side) and the top hemisphere the medial view (i.e., the surface that shows when cutting the brain vertically into two halves). The white line roughly separates the premotor and motor area from the PFC. The corpus callosum is a large fiber bundle connecting the two hemispheres. In the left hemisphere, Broca's region has classically been associated with language production and Wernicke's region with language comprehension (*see* Lateralization of Language as Demonstrated by Brain Imaging Procedures).

language implicate the same language regions that are active during word and sentence processing. Additional brain regions are recruited such as the anterior regions of the temporal lobe possibly reflecting semantic and episodic memory integration processes. The dorsomedial region of the PFC is also activated which has been interpreted as reflecting conscious strategic processes. Integrating text information seems to additionally involve regions of the anterior temporal and parietal cortex.

Although neuroimaging studies on discourse, nonliteral, and figurative language and aspects of social cognition have accumulated, reconciliation of the findings is still difficult as the studies use different stimuli, tasks, terminology, and imaging techniques. The picture that emerges so far is still rough, needs further work and confirmation and thus should be considered rather a basis for discussion than the established truth.

This article is a revision of the previous edition article by S.C. Levinson, volume 17, pp. 11948–11954, © 2001, Elsevier Ltd.

Abstract

Linguistic pragmatics is defined, for the purposes of this article, as the science of language use. Its roots in linguistics, psychology, anthropology, and especially semiotics and the philosophy of language are briefly described. Then some basic notions of pragmatics are reviewed: deixis and indexicality, forms of implicit meaning such as presupposition and conversational implicature, speech acts, and conversation. Major considerations for a definition of the field are introduced: the view of language as action, the role of cooperation and coordination, the importance of common ground and context, the distinction between coded and inferred meaning. The major approaches and traditions are briefly described, as well as interdisciplinary interfaces linking pragmatics to other fields in the humanities and social sciences. The article concludes with a cursory look at current trends and perspectives.

Within linguistics, pragmatics is most easily defined as the science of language use. Its deeper roots go back as far as Graeco–Roman antiquity, with its theory of moods (relating grammatical categories such as indicative, interrogative, and imperative with types of sentence usage in the form of statements, questions, and commands) and with Aristotelian principles of rhetoric. Its more recent history can be traced to a multiplicity of nineteenth and early twentieth century theories of language in various European countries and in the United States (cf Nerlich and Clarke, 1996). I restrict myself to mentioning just a few – largely early- to mid-twentieth century – precursors. The German psychologist and linguist Karl Bühler (1879–1963), for instance, developed an integrated theory of language as system and language in use. He is best known for his 'organon model' of the linguistic sign: in relation to the world, it is a symbol performing a representational function; in relation to the speaker's consciousness, the sign is a symptom or index with an expressive function; in relation to the addressee it is signal with an appellative function. In France, Émile Benveniste (1902–76) developed his theory of enunciation (*énonciation*). He attributed to language, the property of being foundational for human thought, society, and subjectivity. In his view, therefore, meaning is generated in the very act of enunciating or using language. In England, the Polish anthropologist Bronisław Malinowski (1884–1942) emphasized the socio-cultural functioning of language, introducing notions such as 'phatic communion' and 'context of situation,' the latter playing an important role in the development of John Rupert Firth's (1890–1960) contextualist and functionalist linguistics. For Firth, meaning, context, and human behavior were inseparably related, a fact to be taken into account for the analysis of language at all levels of structure, from the phonetic to the sociolinguistic. Meanwhile, Ludwig Wittgenstein (1989–51) developed his later philosophical ideas, focusing on the constitutive role of 'language games' and the importance of looking at the meaning of utterances in relation to their use. In the United States, pragmatism emerged as a philosophical method aimed at the clarification of the meaning of signs and the facilitation of communication. The earlier pragmatist work by, i.a., Charles Sanders Peirce (1939–14) and William James (1842–1910) eventually led to Charles Morris' (1901–79) classical definition, in the context of a general theory of signs or semiotics, of pragmatics as the study of the relation between signs and their users or interpreters (as distinct from syntax, studying the relationships of signs with other signs, and semantics, investigating the relation between signs and the objects to which they are applicable).

If the deeper roots of pragmatics are multidisciplinary, so is its development within linguistics from the early stages in the 1960s and 1970s. Two major sources of inspiration were philosophical: John Austin's (1962) theory of speech acts, further elaborated by John Searle (1969), and Paul Grice's (1989) theory of meaning, and in particular of conversational implicature – a concept to be explained below. Emphasizing historical continuity, it is interesting to know that the seminal contributions by Austin and Grice were first presented in 1955 and 1967, respectively, as William James lectures at Harvard. Further links with other disciplines will be pointed out along the way in the following pages.

After introducing some of the basic notions that consistently appear throughout the pragmatics literature, a few paragraphs will be devoted to the question of how to define the field. Different approaches or traditions in linguistic pragmatics will then be presented, as well as some of the main interdisciplinary interfaces. This article ends with a cursory look at current trends and future perspectives.

Basic Notions in Linguistic Pragmatics

Though principles relating language structure to language use, i.e., pragmatic principles, entered various traditions of linguistic scholarship much earlier, it was not until the 1960s and 1970s that systematic attention to them gathered strength in linguistics and started to adopt the 'pragmatics' label proposed in semiotics by Morris (1938). A strong impulse came from generative semanticists (George Lakoff, Robin Tolmach Lakoff, James D. McCawley, John R. Ross) who countered the Chomskyan generative grammar view of a purely

syntactic deep structure. They argued that contextual information had to be brought in to explain the functioning of linguistic structures. A typical example of how this could be done was provided by Gordon and Lakoff (1971) in their formulation of 'conversational postulates' for deriving the indirect meaning of an utterance from its literal meaning: if someone says *Can you help me?* in a context in which this cannot be simply a question for information (because, e.g., the hearer's ability to help is obvious), then the interpretation *I request you to help me* is generated by an inference rule that says that stating or questioning a felicity condition on a speech act (the assumed ability to comply with a request being a felicity condition on requests) in a context that blocks the literal interpretation of that statement or question (e.g., because of its being obvious), counts as a performance of that act. These kinds of considerations rapidly gained ground in a significant segment of the professional world of linguists, resulting in the straightforward pursuit of typically pragmatic topics. Some of the basic notions that structured the development of the field include deixis, conversational implicature, presupposition, speech acts, and conversational structure (each one, not incidentally, forming the basis for a chapter in Levinson, 1983).

Deixis

A first notion connecting linguistic form to contexts of use is 'deixis,' the label for linguistic devices (called 'indexicals') pointing at the way in which a given utterance relates to dimensions of time, space, society, and discourse (i.e., 'indexicality'). Temporal deixis, e.g., marked with verbal tenses and temporal adverbs (*now*, *yesterday*), locates an utterance in time, taking the moment of speaking or writing, the time of utterance, as the deictic center. Similarly, the contextual dependency of utterances on location in space, or spatial deixis, is carried by adverbs (*here*, *there*), demonstratives (*this*, *that*), directional verbs (*come*, *go*), and the like. Social deixis comprises first of all person deixis, indicated (in English) with personal pronouns, but also attitudinal deixis, as when indexical expressions (including elaborate systems of honorifics in certain languages) signal aspects of social status or forms of respect. In Amharic (an Ethiopian language), e.g., second-person singular male pronouns show four degrees of respect, from insulting, over familiar and intermediate, to highly respectful. Sometimes a distinction is made between relational social deixis (bearing on interactional positioning: speaker–addressee *I–you*, speaker–referent *I–he/she/they*, speaker–bystander *I–we*, where *we* refers to the speaker plus at least one other person present who is included as the source of what is said) and absolute social deixis (referring to relatively stable properties of personhood such as gender). We speak of discourse deixis, finally, when a form of expression (such as *This article will explain*…) refers to earlier, simultaneous, or later discourse, which is then often metapragmatically characterized as a specific type of discourse activity (*article*, *explain*).

Though the phenomenon was studied much earlier by Charles Sanders Peirce, Otto Jespersen, Karl Bühler, Émile Benveniste, and Roman Jakobson, to name just a few, a seminal contribution that placed it at the core of much pragmatic research, was Fillmore (1975).

Implicit Meaning

The reinterpretation of *Can you help me?* as *I request you to help me*, arrived at by means of an inferential process described as a conversational postulate by Gordon and Lakoff, exemplifies a large class of phenomena consisting of aspects of meaning that are not directly or not completely encoded in the form of linguistic expressions, but that are nevertheless communicated thanks to reliance on prior or accessible knowledge on the part of the interlocutors. Utterances do not only anchor language use in context (the case of deixis), but they also make assumptions about it.

A clear case of implicit meaning is that of 'entailment' or 'logical implication.' The definite article *the* in *John is the vice-chancellor* logically implies or entails that John is *a vice-chancellor*. This is a truth-conditional phenomenon: A entails or logically implies B if and only if every situation that makes A true also makes B true. This is different from what Grice called 'conventional implicature,' which does not involve truth-conditionality: the two utterances *John is smart and reliable* and *John is smart but reliable* have the same truth conditions, but the *but* in the second utterance conventionally implicates that there is a contrast and possible incompatibility between being smart and being reliable.

Another type of implicit meaning is 'presupposition.' Presuppositions, or meanings that must be assumed, understood, taken for granted in order for an utterance to make sense, are triggered by a vast range of linguistic forms and structures, from definite descriptions (e.g., *the king of France* presupposing that the king of France exists) to factive verbs (e.g., *to regret*, presupposing that what is regretted is a fact, or actually happened), cleft constructions (e.g., *It was John who left early* presupposing that someone left early), and counterfactuals (e.g., *If only the weather were better* presupposing that the weather is bad). A basic property of presupposition is that it remains constant under negation: the existential presupposition of *The king of France is bald* remains unchanged in *The king of France is not bald*.

A type of implicit meaning which much attention has been devoted to in the linguistic pragmatic literature, though – like implications and presuppositions – originally discussed in philosophy, bears the label of 'conversational implicature.' Paul Grice (see Grice, 1989), whose term this is, suggested that conversations are regulated by a principle of cooperation (according to which conversational contributions should be made in such a way as to satisfy the interactional purposes and needs of the moment) and a number of maxims of conversation (such as, do not say less or more than is required, say only what you believe to be true, be relevant). If a maxim appears to be violated, the assumption that the speaker is still adhering to the principle of cooperation will generate extra meaning beyond what is literally said. Thus *There is a garage around the corner* in response to *I am out of petrol* conversationally implicates that the speaker assumes the garage is open and has petrol for sale; otherwise the answer would cease to be relevant. A conversational implicature is called 'particularized' if and only if an utterance triggers it "only by virtue of specific contextual assumptions that would not invariably or even normally obtain," while it is considered 'generalized' if and only if it is normally inferred from an utterance "*unless* there are unusual specific contextual assumptions that defeat

it" (Levinson, 2000, p. 16). Thus *Some of the guests are already leaving*, uttered in response to *What time is it?*, gives rise to the generalized conversational implicature that not all of the guests are already leaving, and to the particularized conversational implicature that it must be relatively late (otherwise it would not be sufficiently relevant in the given context of the question that is asked). The same utterance would, in response to *Where is John?*, trigger the same generalized conversational implicature (since *some of* generally implicates *not all*, irrespective of the context, unless very specific circumstances arise), while a particularized conversational implicature (on the assumption of the relevance of the utterance in the context) would be the suggestion that perhaps John has already left. Generalized conversational implicatures consist in implicit meaning that can be conventionally inferred from forms of expression in combination with assumed standard adherence to Grice's conversational maxims, while particularized (occasion-specific) conversational implicatures constitute a type of implicit meaning inferred from the apparent flouting of a conversational maxim in combination with assumed adherence to Grice's cooperative principle.

Speech Acts

The idea that speaking is a form of social action has a long and complex history. But the notion of speech as action, as picked up in linguistic pragmatics, found its crystallization in Austin's (1962) and especially Searle's (1969) formulation of speech act theory. Very briefly summarized, Austin's attention was first attracted by a class of utterances with which speakers do not simply say something (e.g., *John will come to your party*, a constative in his terminology) but with which they clearly perform an action (such as the act of promising in *I promise to come to your party*, a so-called performative, in this case more specifically an explicit performative – in contrast to the primary performative *I will come to your party* – because the act performed is also named). This type of utterance had already been the focus of attention for a number of linguists. But for Austin further reflection on this phenomenon led to a rejection of the simple dichotomy between constatives (in which something is said that can be evaluated along the dimension of truth or falsity) and performatives (in which something is done that can only be evaluated in terms of so-called felicity, i.e., appropriateness in relation to aspects of context). Constatives, after all, can also be infelicitous (e.g., when the speaker does not have adequate evidence for what is said), and performatives usually have a propositional content. Therefore, he concluded that all utterances are sayings and doings at the same time, containing 'locutions' (acts *of* saying what is said, the proposition), 'illocutions' (what is done *in* saying something, such as making a statement, making a promise, giving an order), and 'perlocutions' (what is done *by* saying something, i.e., the effect that is scored, such as imparting a belief).

Ignoring the perlocutionary aspect, Searle transformed this approach into his speech act formula F(p), where F stands for illocutionary force, the action side of every speech act, and p for the content or proposition (consisting of a reference and a predication). Searle also developed a systematic way of describing speech acts in terms of various types of felicity conditions, or, as conceived in his theory, necessary and sufficient conditions. For the speech act of promising, for instance, one can formulate a propositional content condition (p specifies a future action by the speaker), preparatory conditions (the speaker is capable of doing what is promised, and under normal circumstances it is not obvious that the action specified would be undertaken), a sincerity condition (the speaker intends to do what is promised), and an essential conditions (the speaker's utterance counts as a commitment to a future course of action).

On the basis of this descriptive apparatus, from which three focal points are distilled (psychological or mental state, the 'direction of fit' between words and world, and the 'illocutionary point') five categories of speech acts are distinguished: assertives (e.g., statements; expressing a belief, making words fit the world, and committing the speaker to the truth of what is asserted), directives (e.g., requests; expressing a wish, making the world fit the words, and counting as an attempt to get the hearer to do something), commissives (e.g., promises; expressing an intention, making the world fit the words, and counting as a commitment for the speaker to do something in the future), expressives (e.g., apologies; expressing a variety of psychological states, having no direction of fit between worlds and words, and simply counting as the expression of a mental state), and declarations (e.g., baptizing; not expressing any psychological state, making both words fit the world and the world fit the words, and bringing about a change in – usually institutional – reality).

Special attention was also paid to a category of indirect speech acts: acts with a communicative force different from the one typically associated with the form of expression. An example is the question *Can you help me?* with which we opened this section on basic notions, and the subsection on implicit meaning in particular.

Conversation

Actual language use is not as neat as speech act theory makes it look. For one thing, most language use may be organized around units and structures that cannot so readily be described in terms of individual, mostly sentence-based, speech acts. In the development of pragmatics after Levinson (1983), a vast proportion of the research that does not deal explicitly with written language, has concentrated on forms or aspects of conversational interaction, whether or not in the framework of 'conversation analysis' (or CA) in the strict sense.

In contrast with the other basic notions, with a firm basis in linguistics, semiotics, and philosophy, the interest in conversation entered linguistics from sociology. A strong impulse came from the work of Harvey Sacks in the 1960s (as collected in Sacks, 1992), whose project was to investigate levels of social order as revealed in the structural organization of everyday conversational language use. Sacks was himself inspired by Garfinkel's (1967) ethnomethodological interest in practical reasoning and Goffman's (1963) focus on the structural significance of aspects of face-to-face interaction. Garfinkel's program was directly influenced by Husserlian phenomenology the implications of which were applied to the social sciences by Alfred Schuetz, in whose view social life is mainly structured around shared meanings. It is those shared

meanings that ethnomethodology extracts from primary phenomena such as commonplace activities and everyday social interaction.

Parallel to, and in interaction with, the development of CA, anthropologists such as Dell Hymes and John Gumperz developed an ethnography of speaking, a theory of communicative competence, and eventually a form of interactional sociolinguistics using conversations as primary data (Gumperz and Hymes (Eds.), 1972; Gumperz, 1982).

Defining the Field

The above notions have more in common with each other than the somewhat artificially separated manner of presentation would suggest. Spelling out all the conceptual connections is not possible in the context of this article. But we cannot avoid the question as to what exactly binds all these topics in such a way as to warrant their treatment under the unifying flag of linguistic pragmatics. There are several definitional threads that intertwine in a variety of ways, giving rise to different approaches and traditions. I just list them here.

- The primordial idea underlying pragmatics is the view of 'language as action.' There is no language without language use. Language does not simply consist of structures that can be systematically related to abstract meanings. It is fundamentally an intricately structured instrument to communicate or elicit information, to persuade, to provoke actions, to make commitments, to express one's feelings, to bring about institutional changes. Such functionalities, to which the structures of the instrument are well-adapted, underlie an endless range of activities such as buying bread, answering the phone, exchanging gossip, searching the internet, interviewing a politician, banning arms sales, delivering a campaign speech.
- The actions or activities presented as instances of language use are all forms of 'social action.' In other words, they involve some kind of 'interaction' between different people, even if this is not immediately transparent. It is this aspect of language use that gives rise to the centrality of the notion of 'cooperation' – the basis of a second definitional thread. Avoiding an exclusively harmony-oriented connotation of the term, it is possible to emphasize an aspect of 'coordination.' Even the most noncooperative communicative exchange, or the most unharmonious form of impoliteness, requires some sort of coordination or, in Clark's (1996) terms, 'joint action.' A more recent terminological alternative is 'co-participation' (Hanks, 2012), which allows for mutuality and reciprocity as well as antagonism and challenge. The exact nature of the interactional dynamics that is involved, and the implications of agency or the role of individual intentionality, remain some of the most crucial points to be elucidated in a theory of pragmatics.
- Coordination, cooperation, or joint actions all require interlocutors who share some kind of 'common ground.' Meaningful interaction between people takes as its starting point implicit assumptions about the extent to which knowledge, goals, and attitudes are shared or fail to be shared, and such assumptions can be adjusted in the course of a verbal exchange. Assumed common ground goes further than mutually presupoposed knowledge facilitating the recognition of intentions. What is involved, ultimately, is everything that has come to be discussed under the labels of 'context' and 'contextualization' – the core of a third definitional thread we must mention. In fact, one of the most common ways of distinguishing pragmatics from semantics has been to define semantics as the study of meaning without context and pragmatics as the study of meaning in context. Though this is a complicated and controversial issue, there is no doubt about the centrality of contextual considerations for pragmatics. A useful starting point for a theorization of context is to be found in the phenomenon of indexicality.

While these three appear, in one form or another, in most pragmatic traditions, there are three more definitional threads, focusing on units of analysis, the role of speaker and hearer in the meaning generation process, and specific cognitive processes, that underlie specific approaches.

- As to units of analysis, it is common practice to distinguish between sentences and utterances. When this distinction is made, it is generally suggested that pragmatics must deal with utterances, i.e., actually produced sentences in their context of production. There is a French pragmatic tradition, which is entirely focused on the corresponding notion of *énonciation*. Extending the idea, discourse – less associated with smaller sentence-length structures – is often identified as the true unit of analysis for pragmatics. The sentence–utterance distinction triggered the corresponding notions of sentence meaning (the province of semantics) and utterance meaning (the domain of pragmatics), to which the more specific notion of speaker meaning can be added. The latter is essentially Gricean 'nonnatural meaning' focusing on the speaker's communicative intentions, which also play a crucial role in orthodox speech act theory.
- Moving away from an exclusive focus on the contribution a speaker's intentions make to the meaning of an utterance, a distinction has been introduced between meaning that is 'coded,' as opposed to meaning that must be 'inferred.' Coded meaning, meaning that is directly attached to the linguistic code, is then regarded as the domain of semantics, while pragmatics studies meaning that cannot be read from the linguistic form directly but that is arrived at through processes of interpretation or inferencing. This is the definitional criterion handled, for instance, by Ariel (2010). The coded versus inferred dichotomy is also reflected in theories of pragmatics that place implicitness at its definitional core.
- Principles of language use adduced to define the field of pragmatics have often been formulated in cognitive terms. While aspects of cognition are involved in everything we do with language, widely accepted attempts have been made to reduce all pragmatic explanation to relatively straightforward principles such as 'relevance' and 'economy.' Keeping things simple for the sake of this quick overview, Sperber and Wilson's (1986) relevance theory, for instance, restricts pragmatics to the investigation of inferential computations

of meaning that handle relevance as the primordial principle (thus streamlining the Gricean approach, while clearly building on it), further supported by a principle of cognitive economy that allows language users to invest precisely the amount of cognitive processing effort that is needed to achieve contextually desirable communicative effects.

Clearly, the enumerated properties of and perspectives on language use lead to a wide range of different approaches and traditions, some of which are reviewed below.

Major Approaches and Traditions

The main divide in the pragmatic landscape is between an orientation that narrows down the field to what is felt to be a linguistically manageable and relatively clearly demarcated area, and an orientation that broadens the field to everything of relevance that can be said about using language as a human activity. The distinction is often described, inaccurately, as one between an Anglo-American and a Continental European tradition. In Yan Huang's words, in the Anglo-American conception "pragmatics is defined as the systematic study of meaning by virtue of, or dependent on, language use" (Huang, 2007, p. 4), focusing on topics such as implicature, presupposition, speech acts, and deixis, and positioning pragmatics in contrast to phonetics, phonology, morphology, syntax, and semantics as an additional component of a theory of language, quite distinct from the interdisciplinary areas of anthropological linguistics, sociolinguistics, and the like. For the Continental European tradition, on the other hand, "pragmatics is defined in a far broader way, encompassing much that goes under the rubric of sociolinguistics, psycholinguistics, and discourse analysis" (Huang, 2007, p. 4), and representing a general functional perspective on every possible aspect of linguistic behavior, in line with Morris' (1938) all-inclusive definition of pragmatics as the study of whatever relations there are between signs and their users or interpreters.

Without going into questions concerning the accuracy of the labels, there is indeed a contrast between a narrower view of pragmatics, treating it as a component of linguistics directly related and opposed to semantics, and a broader view that handles it as a general usage-oriented perspective on language. The basic idea behind what came to be called the perspective view (cf Verschueren, 1999) was very simple. Pragmatics can briefly be characterized as the science of language use, as I did in the first line of this article. When using language, all levels of linguistic structure are involved. Therefore, there are pragmatic aspects, describable and explainable in terms of usage conditions and processes, to be situated in relation to every unit of linguistic analysis, no matter whether they have already been assigned to the realm of one of the traditional components of a linguistic theory, from phonetics to semantics. Similarly, using language involves cognition, social structures, and cultural context. Therefore, much of what finds its way into the hyphenated, interdisciplinary fields of linguistics, must also be relevant to pragmatics.

Within the narrower version of pragmatics, significant developments have taken place in the past few decades. The classical Gricean theory of conversational implicature, for instance, has given birth to a number of so-called neo-Gricean approaches (Horn, 1984; Levinson, 2000; Huang, 2007); it is in this context that Levinson's theory of generalized conversational implicature must be situated. But there is also a tradition that is sometimes called postGricean. Here we encounter relevance theory, which, in Carston's (2009) account, draws a different distinction between implicit and explicit meaning. If Max's question *How was the party*? is responded to by Amy with *There wasn't enough drink and everyone left early*, there is not only the fully explicit linguistically encoded meaning (there was not enough drink + everyone left early), but also a level of 'explicatures': there was not enough ALCOHOLIC drink to satisfy people + everyone WHO CAME TO THE PARTY left early. These meaning enrichments, according to this account, must still be regarded as part of the explicit meaning because the truth or falsity of the utterance will be judged in terms of them. This contrasts with meaning that is wholly pragmatically inferred: given what one knows about parties, Amy's utterance means that the party was not a success. (For a further discussion of such issues, see Recanati, 2010.)

As to the broader perspective view of pragmatics, we find less coherent lines of theory formation, simply because of the open-endedness of the endeavor. If using language consists in the continuous making of linguistic choices, they are never made in isolation: cognition, society, and culture are involved. Some choices are made automatically, some consciously, but all choices are at least potentially subject to reflexivity, i.e., metalinguistic or metapragmatic awareness. Some are made for language-internal structural reasons (the possibilities and limitations of the available resources), others are driven by real or perceived aspects of the circumstances of use, motivated by beliefs, desires, intentions, expectations, or by those attributed to others in the context of interaction. Choices have to be made at all levels of structure, from the choice of a language, code or genre to phonetic/phonological, morphological, syntactic, lexical, semantic details. They may range over variety-internal options, or they may involve regionally, socially, or functionally distributed types of variation. Speakers do not only choose forms; they also choose strategies (e.g., deference), which in turn have an impact on structural choices. Furthermore, choices are made both in producing and in interpreting an utterance.

In order to make sense of this complex process, Verschueren (1999) proposes three key notions for pragmatics: variability, negotiability, and adaptability. Variability is the property of language that defines the range of possibilities from which choices can be made. This range is itself dynamic, as it is not only subject to diachronic change or instant innovation, but also to variable degrees of accessibility for different speakers or for the same speaker at different moments. Moreover, at any given moment in the course of interaction, a choice may rule out alternatives or create new ones for the current purposes of the exchange – though these effects can always be renegotiated, which brings us to our second key notion. Negotiability is the property of language responsible for the fact that, in spite of conventions and default options (cf Levinson, 2000; Jaszczolt, 2005), choices are not made mechanically or according to strict rules or fixed form–function relationships, but rather on the basis of highly flexible principles and strategies. Negotiability, which implies

both rationality and reflexivity, is also necessary because of significant degrees of indeterminacy on the side of the language producer (who is under an obligation to make choices even when the ideal ones are not directly accessible at a specific moment in the exchange) and the interpreter (whose understanding is based on choices that do not necessarily exclude their alternatives from the world of interpretation). Language use as choice-making from such a variable range of options in such a negotiable manner would not be understandable without positing a high degree of adaptability as the property of language that makes all this possible in such a way as to meet – to a satisfactory degree – human communicative needs.

This notion of adaptability is clearly related to the biologically adaptive emergence of human language itself (cf Verschueren and Brisard, 2009). Without going into any of the details here, the origins of language may be related to the twin phenomena of reflexivity and theory of mind, which are human ways of handling social complexity. The concept of 'reflexiveness' or 'reflexivity' (playing a prominent part in social psychology ever since Mead, 1934), refers to the capacity of the mind to bend back upon itself, to be aware of its own experiences as residing in a self that is situated in a social context of interaction. That social context consists of other selves which, by a transformation of reflexiveness which is commonly called 'theory of mind,' are perceived as minds comparable to the self. It is this step that is identified by Tomasello (1999) as the distinguishing trait that allowed *Homo sapiens* to engage in a rapid process of cumulative cultural learning: the basic human biological adaptation compared with other primates is one for living socially. It is a moral step, because by recognizing the other as related to oneself, a subject is itself introduced into a community of 'persons,' conscious agents engaged in reading each other's minds, which enables them to set up common goals. It is this adaptation for living socially that has produced the 'sociality' recognized in Enfield and Levinson (Eds.) (2006) as the key to understanding not only language, but the essence of cognition, culture, and human interaction generally.

Interdisciplinary Interfaces

Needless to say that pragmatics is characterized by plenty of intralinguistic interfaces. Especially the relationships between pragmatics and grammar or syntax, or between pragmatics and semantics speak to the imagination. Bridging syntax and semantics in relation to pragmatics, there are numerous pragmatic studies of information structure. Also the connection with speech sounds, and in particular prosody, claims a lot of attention, and fields have developed such as morphopragmatics. But in the context of this encyclopedia, interdisciplinary connections seem more pertinent.

Irrespective of the position one takes, pragmatics does not exist without its interfaces with differently oriented endeavors in the study of language. As shown above, historically formative traditions that have shaped pragmatics are to be found in semiotics, philosophy, psychology, anthropology, and sociology. During the past few decades, fruitful interfaces have been established, re-established, or developed, with fields ranging from psychotherapy to artificial intelligence. Here I can just hint at a few noteworthy tendencies.

A first tendency that should not escape notice in the interface between pragmatics and neighboring disciplines, with a crucial impact on what language use is supposed to be as an object of investigation, is the forceful re-establishment of the connection between pragmatics and semiotics. While the linguistic pragmatics of the 1970s (roughly) had a tendency to grow away from the larger family of students of sign systems, today some kind of reintegration has become inevitable as a result of the growing awareness that language use itself cannot be fully understood as a separable mode of communication and expression, i.e., outside of a context in which also nonverbal aspects of communication play a vital role: facial expressions, gaze, gesture, proxemics, position in and movement through space, and the like. The importance of these aspects of what has come to be referred to as 'multimodality' has been strengthened in recent decades by the incremental availability of new communication tools such as mobile phones and computers, which affect basic modes of communication such as speech sounds or still and moving images in conjunction with verbal output.

Second, the identity of academic fields dealing with cognition, society, and culture – the traditional points of reference for those who accept the fundamental interdisciplinarity of pragmatics – has undergone significant changes. In particular, they have themselves interdisciplinarily grown together. Vygotsky's early twentieth-century recognition of the social grounding of the cognitive functioning of the human mind (see Mead, 1934; Vygotsky, 1978) – forgotten or discarded by many cognitivists – has been revived as a clear awareness of the cultural basis of human cognition and the social nature of the brain (Tomasello, 1999). Even truth has recently been described as a matter of socio-cultural practices (Dupret, 2011). Maybe the strongest expression of the merging of foci is to be found in the newly foregrounded notion of human sociality (mentioned above, cf Enfield and Levinson (Eds.), 2006), introduced as a cover term for socially oriented and culturally shaped cognition, capable of reflexively monitoring and hypothesizing other people's mental states (perceptions, knowledge, intentions) and their hypotheses about our own, and explaining the fundamental properties of language use in social interaction, whether in face-to-face contexts or at the level of large and complex social and political structures. In line with this is also renewed interest in the ritual functions of speech (Senft and Basso (Eds.), 2009) and in linguistic relativity, i.e., the idea that language structures and ways of looking at the world are not independent of each other (e.g., Gumperz and Levinson (Eds.), 1996). At the present state of research, pragmatics can no longer pretend to be the science of language use without taking the full complexity of human capacities and practices into account. There is no language use without cognition, culture and society, no cognition without culture and society, nor culture and society without cognition and language use. It is not surprising, then, that overlaps and interfaces with sociolinguistics, psycholinguistics, and anthropological linguistics are abundant, and that they sometimes lead to newly labeled endeavors such as cognitive pragmatics and intercultural pragmatics.

Finally, there is a large number of necessarily interdisciplinary areas of application. Thus pragmatics offers insights for forensic work (Coulthard and Johnson, 2007) and the treatment of patients with language disorders (Perkins, 2007). Pragmatically oriented linguists contribute to the discussion of socially and politically relevant issues. Sometimes these efforts bear the label 'critical discourse analysis' (Wodak and Meyer (Eds.), 2009). Sometimes they take the form of straightforward pragmatic analyses of ideological processes in language use (Verschueren, 2012). Ideology is a particularly appealing area since it mainly concerns meaning that is taken for granted and therefore carried along implicitly in sociopolitically relevant discourse – implicit meaning being one of the core phenomena studied by pragmaticians.

Trends and Perspectives

During the past 10–20 years, the study of language use has been revolutionized by technological developments, with an immediate impact on traditions of research in pragmatics. Clearly, investigations of interactional details, as in CA, would not be possible without audio- and videorecordings, the latter enabling close attention to aspects of multimodality as well. While these tools have been well-established for quite a while, developments in computer software are facilitators we could no longer do without. Computers, moreover, now make it possible to do research on vast corpora. This does not only affect the amount of data that can be studied, but also the way in which certain types of investigation are conducted. Needless to say that there are gains and losses in these developments. There are types of meaning generation processes – the stuff pragmaticians should ultimately be interested in – which are not easily operationalized in a way detectable by computer. But on the other hand, computational pragmatics gives access to phenomena that would otherwise remain hidden. The coming years will no doubt witness further developments that, if used with the necessary care, will keep improving or facilitating the way of working.

In addition to the burgeoning fields of corpus pragmatics and historical pragmatics, increasingly experimental methods are used to investigate meaning-generating processes (Noveck and Sperber (Eds.), 2004). Thus the extent to which speakers incorporate what is 'implicated' into their understanding of an utterance can be tested; for instance, whether the statement 'Max has three children' in response to 'How many children does Max have?' is understood that he has exactly three, can be tested by asking native speakers to judge its truth or falsity in a context where Max has four children. Experimental pragmatics faces the challenge of coping with two levels of verbal communication: instructions on how to perform a task, and the verbal task itself. Moreover, there is something paradoxical in the idea of an experimental pragmatics: pragmatics should keep on open mind for the widest possible range of variables that are involved in language use, while experimentation requires close control over a limited set of variables. Keen awareness of this, however, leads researchers to ever more refined experimental methods.

There are not only technologically facilitated and methodologically innovative trends and perspectives. We currently also see a growing awareness (as in an emerging tendency toward 'emancipatory pragmatics'; cf Hanks et al., 2009) of the limiting, predominantly western, cultural basis of thinking about language use. Conscious efforts to include different perspectives in pragmatic theorizing may lead to unexpected new insights in the years to come.

Pragmatism: Philosophical Aspects

Peter Godfrey-Smith, City University of New York, New York, NY, USA

Abstract

Pragmatism is a philosophical movement which began in the late nineteenth century in the USA and exerted significant influence until around the time of John Dewey's death in 1952. Pragmatism fell from favor for much of the latter part of the twentieth century, but is now seeing a revival. The 'classical' pragmatists are C.S. Peirce, William James, and John Dewey. Their philosophies differed a good deal, but all defended broadly empiricist views of thought and knowledge which emphasize the role of thought in guiding action and reject various traditional empiricist psychological positions. Pragmatists also tend to reject correspondence theories of truth and attempt to ground human knowledge on a special 'foundational' set of beliefs. Prominent English-speaking philosophers associated with pragmatism in more recent years include W.V.O. Quine, Richard Rorty, Hilary Putnam, and Robert Brandom.

Pragmatism began in the late nineteenth century with the work of C.S. Peirce, William James, and John Dewey. Pragmatism's influence subsided after the death of Dewey in 1952, but is seeing a sustained revival. This article will first give a rough summary of characteristic themes in pragmatist philosophy, and then look more closely at Peirce, James, and Dewey. The final section will discuss the transformation of pragmatism in the late twentieth century and new forms it is taking in the twenty-first.

'Classical' Pragmatism

Charles S. Peirce, William James, and John Dewey are often referred to as the 'classical' pragmatists. All three were born and worked in the USA, and all combined their philosophical work with strong interests in other disciplines. The views of the 'classical pragmatists' have common themes but are also dissimilar in many ways. They developed views of thought, knowledge, and related topics which are empiricist in a broad sense but reject much of the psychological picture usually associated with empiricism. The empiricist tradition focused on the connections between thought and sensory experience. The classical pragmatists did so too, but in a way that treated thought in the context of its overall role in the life of a human agent, especially in the guidance of action. The pragmatists also thought that traditional empiricism has too passive and too atomistic a view of the mind.

Pragmatist philosophers generally reject attempts to understand human knowledge by appeal to some special set of 'foundational' beliefs that support all the others. For pragmatism, both specific beliefs and general methods of inquiry should be judged by their consequences, by their usefulness in achieving human goals. Although pragmatists stress the role of knowledge in guiding action and solving practical problems, it is an error to see pragmatism as claiming that the direction of research, or choices between rival theories, should be guided substantially by practical or commercial demands. A detailed account of the relationship between theoretical work and practical goals was only worked out successfully by Dewey, though, as discussed below.

The nature of truth has been a central topic for pragmatists, and a source of much trouble for them in the classical period. Pragmatists generally reject 'correspondence' theories of truth, theories which claim that a true belief or statement is one which represents the world as it really is. After rejecting correspondence, pragmatists have had a difficult time devising an alternative view of truth.

An additional unifying thread in classical pragmatism is more subtle and elusive. The classical pragmatists held that there is an important place in the universe for human choice and initiative (a theme more prominent in James and Dewey than in Peirce). In different ways they opposed philosophical systems which regard the world as 'finished,' 'complete,' or impervious to the effects of choice. Pragmatists also tend to hold 'humanistic' perspectives on matters involving morals and values, opposing both nihilistic views that reject all moral assessment as founded on illusion, and views that locate moral and other evaluative facts outside the everyday world of human striving and well-being.

Charles Sanders Peirce (1839–1914)

Peirce's career began well but ended very badly, without him ever having held a long-term academic position. His writings are very ambitious but often disorganized. He evaded obscurity, and at times sheer expiration, largely through James's support.

Peirce's most important works discuss the relations between doubt, inquiry, belief, and action. His central texts on these topics are two papers which appeared in the *Popular Science Monthly*, *The Fixation of Belief* in 1877 and *How to Make Our Ideas Clear* in 1878. Peirce also wrote a good deal about logic, measurement, the theory of signs (which he called 'semiotic'), probability, evidence, and some speculative cosmological ideas (Buchler 1955; Misak 2013).

Peirce argued that inquiry always begins with 'real and living doubt' which he distinguished from the feigned doubt of Descartes. Doubt prompts inquiry, which aims at belief. Peirce claimed that the essence of belief is the establishment of a habit of action. Alexander Bain had made this suggestion in

the mid-nineteenth century, within the framework of an associationist psychology. Peirce and other pragmatists made this link between belief and action central to their philosophies. Peirce believed that science is the most effective method for relieving doubt and acquiring useful habits of action. His defense of science emphasized the cumulative, long-term, and social properties of scientific inquiry, especially the tendency of scientific testing to produce a 'convergence' of belief among people who start from different positions.

In his paper *How to Make Our Ideas Clear*, Peirce argued for a principle which later became famous as 'the pragmatic maxim.' Peirce said that to work out what the meaning of a 'conception' is, we should work out "what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object." This principle is obscure and was later paraphrased by James, Peirce, and others in a number of conflicting ways. One possible interpretation is to see the famous 'maxim' as expressing a fairly familiar empiricist view – that our concept of any object is just our concept of its possible effects on our experience. Then the novelty in Peirce's paper lies in his attempt to derive this empiricist principle from an unusual starting point – a theory of the role of belief in guiding action. Some later discussions in Peirce and James treat the maxim itself as a claim about how the meaning of a belief or set of beliefs (a 'conception') is found in its effects on the believer's action.

In the same paper, Peirce also gave a definition of truth. He said that what we mean by 'the truth' is the opinion which is "fated to be ultimately agreed to by all who investigate," or in another formulation, the opinion that will be held at the limit of scientific inquiry. Both here and elsewhere, Peirce treated topics in epistemology and the philosophy of science in ways that placed much emphasis on the social context of testing and investigation.

William James (1842–1910)

James made pragmatism famous, especially in his 1907 book *Pragmatism*, the most widely read of all pragmatist writings. James had a brilliant and influential career based at Harvard, in both philosophy and psychology.

James wrote a number of important works before he began calling himself a 'pragmatist' and aligning his views with those of Peirce. In his earlier philosophical works, James argued that we have the right to actively choose sides on momentous, unresolved philosophical issues that will affect how we live our lives (James, 1897/1956). Choices made on these issues will be strongly affected by our individual temperaments; we should not expect all individuals to find the same philosophies appealing. The issues James applied this doctrine to included the existence of God, the freedom of the will, and the reality of moral facts. In this earlier period, James also published a landmark work in psychology, his two-volume *Principles of Psychology* (1890/1950).

From 1898, James began to embed his characteristic themes within an overtly 'pragmatist' framework. He gave credit to Peirce's role in discussions in Cambridge in the early 1870s, in a social circle called the 'Metaphysical Club' (Menand, 2001). To a greater extent than Peirce and Dewey, James took pragmatism to be continuous with the tradition of English-speaking empiricist philosophers such as David Hume and J.S. Mill. James publicized pragmatism with great energy, and transformed it in ways that induced unease in Peirce. James presented pragmatism as a way to avoid the errors of the two key rival philosophies of his day – overly scientistic and materialist empiricism on one side, and sentimental, over-optimistic religious idealism on the other. James endorsed a version of the pragmatic maxim, described earlier, taking it to be a method for finding the real content in philosophical doctrines and disagreements. James argued that when the maxim is applied to many standard philosophical debates, it does *not* typically show that these lack content; instead the maxim reveals hidden and substantial issues that are at stake. These issues, for James, often concern the long-term direction being taken by the universe, and the role of human choice in affecting how things turn out. James saw pragmatism as a way of distilling the genuine human significance from obscure philosophical theories and debates.

James was a less scientistic thinker than Peirce, and more individualistic than Peirce and Dewey. James talked of assessing ideas in terms of their 'cash value,' an unfortunate phrase which led many to interpret pragmatism as vulgar and anti-intellectual. James also invited a stream of criticism through his tendency to discuss the nature of truth in a vague and simplistic way. He said at various times that true ideas are just those that can be verified, or those that are useful. Some of the criticisms of James rested on misinterpretations, but there is no question that he wrote about this topic imprecisely. Despite this, James's writings have endured. His discussions of the role of individual temperament in philosophical choices never seem dated, for example, and James's attractive personality, imagination, and boundless energy radiate from the pages of his work.

John Dewey (1859–1952)

Dewey's work is the culmination of the 'classical' period in the pragmatist tradition. In the course of a remarkably long and productive career, Dewey published in virtually all areas of philosophy and in psychology, education, and politics. He wrote both popular, accessible works and dense, uncompromising ones. Dewey spent his most important years first at the University of Chicago, where he worked in philosophy, education, and psychology, and then at Columbia, where he focused more on philosophy and was also active in politics.

Dewey's work went through several phases. Early in his career he accepted an idealist philosophy of the type influenced by Hegel, and also had Christian interests. Around the turn of the century, he turned toward a more scientific approach to philosophy, influenced by Darwin and by James's *Principles of Psychology*. Around this time, Dewey also dropped his commitment to Christianity. Dewey came to reject all supernatural forms of religion, and did not share James's sympathy for mystical ideas, but he continued to see value in some kinds of religious experience (Dewey, 1969–72, 1976–83).

The scientifically oriented philosophy Dewey developed after 1900 was initially fairly similar to James's pragmatism,

and some of this work influenced and was acknowledged by James. In later decades, Dewey reworked pragmatist themes within what he called a 'naturalistic' framework – a framework which sets out from a biological description of living organisms and their relations to their environments, and emphasizes also the importance of social interaction in human life. Dewey argued that intelligence is a means for humans to transform their environments in order to deal with the problems posed by uncertainty and change in natural events.

In *Experience and Nature* (1925) perhaps his greatest work, Dewey defended his naturalistic view of mind and knowledge, and criticized the philosophical tradition for its postulation of false divides or 'gulfs' – between mind and matter, thought and object, theoretical and practical. The philosophical tradition is plagued by 'dualisms' which lead to pseudoproblems, problems of establishing contact between realms that should never have been set against each other in the first place. The source of these dualisms is a 'split in being' established by the ancient Greeks, a split between the 'perfect, permanent, self-possessed' and the 'defective, changing, relational.' Dewey sought to replace these dualisms with a view based on various kinds of 'continuity' – between mind and nature, between organism and environment, and between cognition and simpler biological capacities. For Dewey, these natural continuities also provide the material needed to resolve oppositions between fact and value. Much of Dewey's later work is a mixture of careful system-building based on assertions of 'continuity' and sweeping historical surveys, tracing the histories of crucial philosophical errors back and forward through thousands of years (Dewey, 1981–90).

Dewey defended a social theory of mind, claiming that thought only exists within a language-using community. He argued that the primary role of science is to help human societies deal with problems and control their environments. But Dewey thought that it was unscientific for scientists to direct their work according to *specific* practical problems. Rather, science is the study of a special subset of properties of natural affairs – relations and connections, called by Dewey 'instrumental' properties. Science is most successful in expanding our capacities for problem-solving and transforming our environment when it is directed on the study of the instrumental features of nature in an open-ended way, unconstrained by immediate practical applications.

Dewey rejected what he called the 'spectator theory of knowledge,' the view that the genuine knower is someone who registers what is going on but does not intervene. Instead, the proper role of knowledge is to enable humans to transform their situations in beneficial ways. This also led Dewey into some of the same arguments that James had with defenders of correspondence or 'copy' theories of truth. Dewey thought that theories of truth as correspondence were aimed at inventing magical relations between thought and the world in order to overcome what he saw as a nonexistent problem – the problem of how the mind and the external world could have any contact with each other. He also thought correspondence theories belong with a spectator view of the role of knowledge. He did not take seriously the idea that 'copying' the world can be a *means* to transforming it; he saw these inevitably as rivals.

Dewey wrote often of the role played by knowledge in 'transforming' or 'reconstructing' the world, but this 'transformation' should not be understood as implying an idealist metaphysical view. Dewey thought that knowledge is a factor in changing things in the world because knowledge has a role in guiding *action*, which transforms things by means of physical relationships. I said earlier that a second thread in the classical pragmatists, in addition to their treatment of thought and action, is a resistance to a 'closed' conception of the universe and an assertion of the significance of human choice. In Dewey's work, this theme, which was developed in a vague and overly cosmic way in James, is given a more down-to-earth treatment. Dewey insisted on the reality of the progressive reshaping of the world by human choice, though this reshaping is limited in scope, contingent in its effects, and draws on craft skills as well as ideas.

Dewey was a significant figure in US political and social thought (Westbrook, 1991). He defended a version of liberalism and wrote extensively about the proper structure of a democratic society. At various times he was attacked by both the right and the left. He hoped for a more 'democratic' economic order, but kept communism at arm's length. Dewey's best known political activity was his chairing of an international inquiry into Stalin's trial of Trotsky. The inquiry entitled its report 'Not Guilty.'

At Chicago, Dewey worked closely with George Herbert Mead, a founder of social psychology in the USA. Mead (1934) argued that human individuality is a product of social embedding; that both cognition in general and specific mental developments such as a sense of self emerge as products of various kinds of symbolic behavior within a community. Dewey also wrote about art and took a lifelong interest in education. When he was at Chicago he established an experimental school. Dewey favored problem-solving as an approach to all types of learning, and his ideas remained influential in education during decades when his name had almost dropped out of English-speaking philosophy.

After Dewey

Dewey's ideas, and pragmatism in general, subsided from philosophical discussion for several decades after Dewey's death in 1952. A primary reason for this was the growing focus on formal logic and the philosophy of language in US philosophy after World War II, prompted especially by the immigration of European philosophers and logicians who defended a rigorous 'analytic' style of philosophy. After Peirce, the pragmatists had not taken an interest in formal logic. Dewey also had idiosyncratic and rather opaque ideas in the philosophy of language, which rapidly came to seem dated.

One of the leaders of the new analytic philosophy, W.V.O. Quine, had significant effects on the perceived viability of pragmatism, and on its interpretation, through some brief remarks in famous works, especially *Two Dogmas of Empiricism* (1951). There, Quine, in response especially to Rudolf Carnap, endorsed what he saw as a pragmatist view of belief change. Quine's emphasis was on conceptual flexibility; he held that even the most basic parts of our network of beliefs (including logical principles) could rationally be modified in response to unexpected experiences. Quine's influence helped keep the idea of a pragmatist epistemology alive, but in a way that

foregrounded some pragmatist themes and backgrounded others in a new way (Godfrey-Smith, 2013). Quine treated beliefs as tools for prediction – in this way, he was closer to the mainstream empiricist tradition. He did not give the link between thought and action anything like the role it had in classical pragmatism.

The most important figure in the revival of pragmatism has been Richard Rorty (1931–2007), who also carried the influence of pragmatism outside of philosophy into neighboring disciplines. Rorty viewed himself as carrying on the tradition of Dewey, and to a lesser extent James. Rorty called himself an 'antiessentialist' about traditional philosophical concepts such as truth, knowledge, and justice. Antiessentialism in this sense is the denial that there is anything general to say, from a philosophical point of view, about the *nature* of truth, the *nature* of justice, and so on. It is possible and worthwhile to give a theory of how the word 'true' functions in ordinary discourse, but pointless to give a theory of truth that goes beyond this (Rorty, 1982).

The continuity between Rorty's ideas and Dewey's is a matter of controversy. Dewey's mature work, as outlined earlier, includes a mixture of sweeping historical stories aimed at dissolving philosophical problems, and careful system building of his own. Rorty endorses the dissolving but not the system building. However, a strong case can be made that Dewey's critical points and his attempts to 'get over' standard debates usually depend on his positive philosophical theories. Moreover, James, as discussed earlier, used pragmatism to breathe new life into metaphysical problems, not to deflate them. As Rorty's views on traditional philosophical questions are so focused on dissolving and deflating, it is in some ways more appropriate to associate Rorty with the later work of Ludwig Wittgenstein rather than with pragmatism. Rorty, however, made a substantial contribution to the development of pragmatist ideas by claiming that the right approach to the problem of truth for the pragmatist philosopher is not to identify the true with the useful, or with the verifiable, but to give a 'deflationary' view of truth (Rorty, 1991). Deflationism, which was developed in the late twentieth century in other parts of the philosophy of language, holds that, to say that a sentence is true is not to say that the sentence has a special correspondence relation to the world, or that it has a special kind of usefulness, but is just to *assert* the sentence, perhaps in a way sensitive to the context of the conversation. We have the word 'true' in our language because it allows us to abbreviate, give credit, and generalize – 'Everything you said about Toyotas is true.' The word 'true' is no more than a conversational tool of that kind.

Many other philosophers in the late twentieth and early twenty-first centuries who have allied themselves with pragmatism have been largely concerned with problems of language, meaning, and truth. These philosophers have also taken on board the emphasis on flexibility in belief change and the rejection of foundationalist views in epistemology that were present in the classical pragmatists and foregrounded by Quine. In some cases, though by no means all, a link to pragmatism is seen as part of an attempt to dissolve or 'get over' traditional debates about mind and knowledge.

Hilary Putnam was for some years a leading defender of a strongly 'realist' set of views about the relation between thought and the world, but he changed his mind, and developed a position he called 'internal realism,' which rejects the correspondence theory of truth and which Putnam allied to pragmatism. Putnam argued that it is not possible for a theory to pass every possible test, and command consensus when all the evidence is in, and yet be false; this view resembles Peirce's theory of truth. Putnam has recently reassessed these issues yet again. Robert Brandom (2010) defends a project he calls 'analytic pragmatism.' This is an approach to language that focuses on the *use* of words and linguistic forms in discourse, as contrasted with making the *meaning* of words primary. This emphasis on use owes much to Ludwig Wittgenstein. Huw Price (2003) also defends a use-based approach to language, rejects the correspondence theory of truth, and sees his pragmatism as strongly deflationary of metaphysical issues, advocating a 'quietist' approach – a resolutely nontheoretical stance – toward many traditional debates. Philip Kitcher (2012) also wants philosophy to move, with the aid of pragmatism, past standard debates in epistemology and metaphysics but is less deflationary about social and moral philosophy, where more substantial work is to be done. Other contemporary philosophers with significant connections to pragmatism include Simon Blackburn, Susan Haack, Cheryl Misak, and Arthur Fine.

In my outline of the 'classical' pragmatists, I emphasized their treatment of the link between belief and action. This, for the classical pragmatists, was an innovation that took them beyond the mainstream empiricist tradition. For better or worse, from Quine onward this theme subsided in 'pragmatist' philosophy. The emphasis instead has been on conceptual flexibility (Quine), rejection of the correspondence theory of truth and representation-based approaches to language (Rorty, Brandom, Price), and finding ways to get beyond sterile philosophical debates (Rorty, Price, Kitcher, Fine). But as the early sections of this article may also have made clear, wholesale opposition to philosophical theorising had little role in classical pragmatism. James, in particular, thought that the significance of standard philosophical debates was, if anything, *under* estimated. Dewey's criticisms of the philosophical tradition were not offered in a free-standing form, isolated from positive views on philosophical topics; the critical and constructive sides of his thought were tied tightly together. So the themes of recent pragmatists differ a fair amount from those of the originators of the movement, but at all stages, including the 'classical,' pragmatism has been a diverse and mutable collection of ideas.

Abstract

'Pragmatism' is the name of an originally American philosophical movement; its classical figures are C.S. Peirce, W. James, J. Dewey, and G.H. Mead. The basic idea of pragmatism is that all cognition is ultimately grounded in practical problem situations. Action is thus conceived as based on 'habits,' but in need of constant creative reorganization. Pragmatism emphasizes a nonfoundationalist understanding of philosophy, the fallible nature of truth, the social nature of the self, the importance of inquiry in all fields of human life, and metaphysical pluralism (R. Bernstein). Pragmatism contributed among other things to the development of semiotics, functionalist psychology, the phenomenology of moral and religious experience, social psychology, and an antideterminist metaphysics. In the writings of Dewey, a radical version of democracy became articulated as the normative core of pragmatism. Although influential in a wide range of social scientific disciplines, pragmatism was marginalized in academic philosophy from the 1950s to the 1970s. In recent years, it has experienced a considerable revival (Rorty, Putnam, Habermas).

'Pragmatism' is the name of an originally American philosophical movement; its classical figures are C.S. Peirce, W. James, J. Dewey, and G.H. Mead. The basic idea of pragmatism is that all cognition is ultimately grounded in practical problem situations. Action is thus conceived as based on 'habits,' but in need of constant creative reorganization. Pragmatism emphasizes a nonfoundationalist understanding of philosophy, the fallible nature of truth, the social nature of the self, the importance of inquiry in all fields of human life, and metaphysical pluralism (R. Bernstein). Pragmatism contributed among other things to the development of semiotics, functionalist psychology, the phenomenology of moral and religious experience, social psychology, and an antideterminist metaphysics. In the writings of Dewey, a radical version of democracy became articulated as the normative core of pragmatism. Although influential in a wide range of social scientific disciplines, pragmatism was marginalized in academic philosophy from the 1950s to the 1970s. In recent years, it has experienced a considerable revival (Rorty, Putnam, Habermas).

Pragmatism is the name usually given to the classical philosophical movement in the United States. It emerged in the last decades of the nineteenth century and achieved a certain hegemony in the country's intellectual life during, and immediately after, the so-called Progressive Era (1896–1914). From the 1930s, and even more after 1945, it was largely displaced by other currents of thought in philosophy, the social sciences, and public political discourse. American pragmatism also attracted considerable attention in Europe, especially around 1910, although exposition and critical discussion of pragmatism displayed widespread misunderstandings and the tendency to depreciate it by reducing it to an expression of alleged American national characteristics.

Pragmatism Defined

The everyday sense of the term 'pragmatic' certainly contributed to these misunderstandings, connoting as it does a kind of 'muddling through' that is oriented to immediate requirements, disregards theoretical or moral principles, and treats the given features of the situation simply as part of a calculation. The term pragmatism has the same Greek roots as praxis, practical, etc. The founder of pragmatism, Charles Sanders Peirce (1839–1914), coined the term as a result of his reflections on Kant's use of the terms 'pragmatic' and 'practical.' Peirce's lectures and writings around 1878 are now regarded as the original documents of pragmatism. These first became known only to narrow circles of intellectuals in Cambridge, Massachusetts, and did not achieve wider notice until some 20 years later, when William James (1842–1910) referred to them in some lectures, but above all through his lectures on 'pragmatism' published in 1907. Peirce came to distance himself from James' pragmatism and to call his own philosophy 'pragmaticism.'

Along with Peirce and James, the inner core of pragmatism is usually taken to include John Dewey (1859–1952) and George Herbert Mead (1863–1931). The differences between all these thinkers were so evident, not least to the 'pragmatists' themselves, that their subsumption into a single school or movement has constantly been questioned. The most widely accepted view, however, has been that despite the differences there is enough of a core of shared views to justify speaking of 'pragmatism' as a distinct philosophical orientation.

What are the basic themes of pragmatism? Peirce's approach starts from his critique of Descartes' methodological principle of radical doubt and the resultant program of making the thinking ego's certainty of itself into the firm foundation of a new philosophy. The pragmatist questions the meaningfulness of Cartesian doubt, not in order to defend unquestionable authorities against the emancipatory claim of the thinking ego, but arguing for a more substantial doubt, that is, the grounding of cognition in real problem situations. In pragmatism, the guiding idea of the doubting ego is replaced by the idea of a cooperative search for truth in order to overcome real problems of action. Real doubt occurs in action, conceived as a cyclical succession of phases. Thus, every perception of the world and every action in it are anchored in an unreflective belief in self-evident conditions and successful habits. But these habitual ways of acting constantly come up against the resistance of the world, which

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03192-5

is seen to be the source of the destruction of unreflective expectations.

The resultant phase of real doubt leads to a reconstruction of the interrupted context. Perception must grasp new or different aspects of reality; action must attach itself to other elements of the world or reorganize its own structure. This reconstruction is a creative accomplishment by the actor. If he or she succeeds, via a change in perception, in acting differently and thus getting going again, then something new has come into the world: a new way of acting that can be institutionalized and itself become an unreflectively followed routine. Thus, pragmatists see all human action in the opposition between unreflective habits of action and creative accomplishments. This also means that creativity is seen here as characterizing achievements in situations that demand a solution, rather than the unconstrained creation of something new without a constitutive background in unreflective habits.

From this basic model of pragmatism, in which action and cognition are combined in a particular way, we can derive the other central claims of pragmatism. In the metaphysics of pragmatism, reality is not deterministic: rather, it enables and demands creative action. In the epistemology of pragmatism, knowledge is not the reproduction of reality but an instrument for dealing with it successfully. The semantics of pragmatism locates the meaning of concepts in the practical consequences for action resulting from their use or their difference from other concepts. Thus in pragmatism's theory of truth, the truth of sentences can only be determined by way of a process of agreement on the success of action based on them, and not on, say, their correspondence with an uninterpreted reality. The misunderstanding of pragmatism as principally a movement aiming at the destruction of the ideal of true knowledge resulted primarily from the isolation of individual sentences, such as some of William James's statements about truth, from the whole complex of pragmatist thought.

Main Variants of Historical Pragmatism

The leading representatives of pragmatism contributed to different fields of inquiry. Peirce was primarily interested in developing a general theory of scientific knowledge and a broadly conceived theory of signs of semiotics. His multifaceted work, which does not deal with questions of social theory, includes important thoughts on the intersubjective use of signs and on the creative production of hypotheses ('abduction'). This theory of signs, particularly in its emphasis on the 'discourse' of scientists in an experimental community, has become very influential.

William James at first worked mainly in psychology, in which he saw the prospect of a way out of the dilemma between a religiously based belief in the free will of the moral agent and the scientific image of the world as a universe governed by causal processes. The solution, for James, lay in the functionality for the survival of the human organism in its environment, which he saw in the human capacity to pay deliberate attention to perceptual impressions and to choose between alternative courses of action. A 'functionalist' psychology could proceed by understanding all mental achievements in terms of their function for the organism's active mastery of its environment.

James elaborated his antideterminist stance in an influential article on *The Will to Believe*, in which he defended the legitimacy of religious experience against scientistic skepticism. This essay also became the point of departure for his wide-ranging study of the varieties of religious experience, in which he founded the empirical study of religion not on religious institutions or theological doctrines, but on the phenomenology of religious experience. In his last years, he began to use the phenomenology of experience as a guideline for the elaboration of a pluralist, nondeterminist metaphysics.

John Dewey, whose thought at first developed rather independently of the first pragmatists, abandoned his earlier neo-Hegelian approach during the 1890s and linked up with the logical and psychological aspects of pragmatism as developed by Peirce and James. He constructed a philosophy that extended the core ideas of pragmatism not only into all the traditional domains of philosophy (metaphysics, logic, ethics, aesthetics) but also, and in particular, into the fields of educational theory and social and political philosophy. He gave more explicit emphasis than the others to a radical version of democracy as the normative core of pragmatism. Taking part in a great number of political controversies, he became one of the most influential American intellectuals ever and *the* representative thinker of the United States.

George Herbert Mead, a friend of Dewey, did most to develop James' strategy of the translation of pragmatist themes into the program of a biologically based empirical social science. His decisive contribution to social theory consists of his theory of the specific features of human communication and hence the attempt to thematize the constitution of personality structures in the dynamics of interpersonal relationships. Mead attacked the assumption of a presocial substantial self and replaced it by a theory of the genesis of the self in which even the interaction of a person with himself or herself is conceptualized to be the result of social structures. Mead also pursued this line of thought in the direction of problems of cognitive development, such as the constitution of permanent objects in experience and the constitution of structures of time. His ethical theory and antideterminist philosophy of history remain rather neglected.

Thus it can be said that pragmatism has never been a clearly delimited school of thought with a fixed research program; it shows, however, the characteristics of an intellectual movement or, at least, constellation with the common elements of antifoundationalism, the fallible nature of truth, the social nature of the self, the importance of inquiry in all fields of human life, and (metaphysical) pluralism (see Bernstein, 1992, 2010). During the first decades, pragmatism exerted a considerable influence on a variety of disciplines in the United States (functionalist psychology, institutionalist economics, educational reform, law, theology, political theory, the Chicago school of sociology). After the 1930s, this influence clearly waned, reaching a nadir in the 1950s and the 1960s (An indicator of this development is probably the fact that the 1968 edition of this encyclopedia did not contain an entry on pragmatism). One of the few currents that kept the heritage of pragmatist social thought alive was the school of symbolic interactionism in sociology, which produced a rich amount of empirical work

mostly on interpersonal relationships, processes of emergence and definition of deviant and subcultural behavior, social movements, and the division of labor in professional organizations. There were other main figures of American sociology at that time in whose work pragmatist orientations can easily be detected (C. Wright Mills, Philip Selznick).

Contemporary Pragmatist Thinking

Since the late 1970s, a renaissance of pragmatist philosophy has been underway. Apart from thinkers like Richard Bernstein and John Smith, who had continuously pursued a pragmatist agenda, two thinkers have probably contributed most to this renaissance. One was Richard Rorty who had for a long time tried to articulate pragmatist motifs within the tradition of analytical philosophy before breaking (more or less) with it and proposing a variant of postmodern thinking that he calls pragmatism. Although Rorty was a perceptive social critic, he had no social theory and actively repudiated the need for it. His philosophy has sparked a vast critical literature and reappropriation of the historical pragmatists; his main rival in these debates was Hilary Putnam in whose work one can find a thorough and significant restatement of pragmatist philosophy.

The other main originator of this renaissance is Jürgen Habermas. Together with Karl-Otto Apel, these two German thinkers gave a new twist to the winded history of the European reception of pragmatism. From the beginnings of the twentieth century, very diverse schools of European thinking had used elements from American pragmatism for their own purposes (e.g., French Catholic Modernism, Italian proto-Fascism, German Philosophical Anthropology, and others). Other European thinkers came close to pragmatism in some aspects of their work (e.g., Max Scheler, Arnold Gehlen, Martin Heidegger, and Ludwig Wittgenstein) without spelling out their relationship with it. Peirce's ideas about the 'discourse' of scientists has been of decisive importance for the 'discourse ethics' developed by Apel and Habermas. Mead's understanding of symbolically mediated interaction has been crucial for the 'Theory of Communicative Action' by Habermas; he declares Mead the main inspiration for 'the paradigm shift from purposive to communicative action,' which he proposes in sociological theory.

Habermas' faithfulness to the pragmatist heritage has been disputed almost as much as Rorty's. There are obviously other possibilities for pragmatist social thought than his combination of a theory of communication with systems theory or than his restriction of the tasks of moral theory to the program of discourse ethics. One can claim (Joas, 1996, 2000) that the most fundamental contribution of pragmatist social thought lies not in its emphasis on communication, but in its specific understanding of the creativity of human action and the emergence of value commitments. This understanding distinguishes pragmatist social thought from approaches focusing on either rational action or normatively oriented action, or from a systems theory or structuralism, which disconnect the dynamics of human action from the development of social wholes. On the basis of pragmatism understood as a theory of the 'situated creativity' of human action, it becomes possible to reconceptualize rationality and normativity and to develop a theory of macrosocial processes and social change (Ansell, 2011) prepared by the political theory and philosophy of history in the works of the classical pragmatists.

Abstract

The prefrontal cortex is the region in the cerebral cortex that includes the tissue that has projections from the mediodorsal nucleus of the thalamus and/or the amygdala and that has extensive projections to the basal ganglia and the rest of the cerebral cortex. Primates have an expanded prefrontal cortex and may have subregions not present in other mammals. The prefrontal cortex participates in extended neural networks with other cortical regions, and especially the posterior parietal cortex. The prefrontal cortex supports cognitive functions that are necessary to organize behavior in time and in context. This includes a form of intelligence, sometimes referred to as fluid intelligence. There are five general categories of symptoms associated with disease of the prefrontal cortex: disturbances of motor function; loss of divergent thinking; environmental control of behavior; temporal memory; and emotion and social behavior.

Introduction: What Is Prefrontal Cortex?

The term 'prefrontal' has an uncertain origin dating back to at least the early 1900s and over time has meant different things to different people. One way to define cortical regions is by considering their thalamic afferents. Thus, the lateral geniculate nucleus defines primary visual cortex, whereas the medial geniculate nucleus defines primary auditory cortex. Using this logic, Rose and Woolsey (1948) proposed that the cortical projection of the mediodorsal nucleus of the thalamus (MD) would define the 'orbitofrontal' cortex of mammals. These authors saw their definition as a way of solving the problem that the frontal region of primates beyond the motor and premotor cortex has a prominent layer IV, and thus was called frontal granular cortex, whereas in nonprimates layer IV is indistinct or absent. Because the MD projection was constant across the mammals they examined and the granular cortex was not, they believed that their definition of orbitofrontal cortex solved the apparent conflict.

One major problem with the Rose and Woolsey definition is that MD is not a homogenous structure and shows large differences in organization and connectivity across mammalian species. The differences in connectivity are not just in the afferents to MD but also in the efferents from different regions of MD. Just because MD projection cortex is present across mammalian phylogeny, it does not mean that the cortex has the same function. We thus must use other criteria in parallel with the Rose and Woolsey definition.

Reep (1984) proposed a different solution to the definitional problem. He proposed that the connections with the amygdala and certain brainstem regions such as the dopaminergic input from the ventral tegmentum, as well as cytoarchitecture be used to make cross species comparisons. Using these criteria he identified five different subregions (see **Figure 1**) present in monkeys, cats, and rats: (1) a medial infralimbic region receiving input from the amygdala but not MD; (2) a medial prelimbic region (Brodmann's areas 25 and 32) receiving input from MD, amygdala, and dopaminergic brainstem; (3) a region of agranular cortex overlying the claustrum receiving input from MD, amygdala, and dopaminergic brainstem; (4) the anterior cingulate region receiving input from MD and the anterior thalamus; and (5) a region of cortex lying between prelimbic and insular areas that receives input from MD but not the amygdala. He noted that other regions, such as area 9/46 of the monkey and human, do not appear to follow any obvious patterns across species and thus may be unique to one or a few orders of mammals.

Wise (2008) has argued forcefully that the unique presence of granular cortex in primates implies that primates have frontal regions that are unique and not found in other species. Pushing this idea further we can argue the common ancestor of living mammalian orders had a prototypical 'prefrontal' cortex, which has been modified and expanded as the brains grew larger. The expansion of prefrontal areas likely began by subdividing the prototypical regions and the eventual development of granular cortical regions may indeed have led to novel functions. Pandya and Yeterian (1985) proposed that the expansion of prefrontal subareas is related directly to the increase in sensory areas and the increase in posterior parietal cortex. Primates are also unique in the expansion of the posterior parietal regions (*see* Cortical Areas Engaged in Movement: Neuroimaging Methods) so it is not a leap to conclude that the prefrontal granular and posterior parietal regions have unique functions.

The granular areas in primates include dorsolateral prefrontal cortex (Brodmann's area 46), dorsal and medial prefrontal areas (different parts of area 9), ventral prefrontal cortex (areas 12, 44, 45, and 47), frontal pole cortex (area 10), and rostral orbitofrontal cortex (parts of areas 11, 13, and 14) (see **Figure 2**). These regions can be functionally divided into four regions namely dorsolateral prefrontal cortex, dorsomedial prefrontal cortex, ventromedial prefrontal region, and orbital prefrontal region, in addition to the adjacent anterior cingulate cortex, as illustrated in **Figure 3**.

The frontal cortex as a whole has a special relationship with the basal ganglia because although virtually all of the cerebral cortex projects to the basal ganglia, the frontal cortex receives most of the return projections via the thalamus (Middleton and Strick, 2000). These projections are present in species as diverse as monkeys and rats and, in addition, in both species there are a number of parallel, apparently functionally segregated circuits (Alexander et al., 1990; Middleton and Strick, 2000; Uylings et al., 2003). For example, there are cortico-basal

Figure 1 The prefrontal cortex. (a) Serial sections through a rhesus monkey brain showing different cytoarchitectonic regions (Brodmann numbers). Dotted areas receive projections from MD; gray areas receive projections from the amygdala. (b) Serial sections through a rat brain showing architectonic areas and MD, and amygdala projection areas as in the monkey. Both species have similar regions of overlap in MD and amygdala projections as well as areas of no overlap. Abbreviations: AON, accessory olfactory nucleus; AC, anterior cingulate; Ac, anterior commissure; CL, claustrum; gcc, genu of the corpus callousm; IL, infralimbic; lag, lateral agranular; MO, medial orbital; PL, prelimbic; plag, posterior lateral agranular; sa, arcuate sulcus; sp, principal sulcus; SEP, septum; TT, tania tecta; vlag, ventral lateral agranular; VLO, ventral lateral orbital; VO, ventral orbital. Modified and adapted from Reep, R., 1984. Relationship between prefrontal and limbic cortex: a comparative anatomical review. Brain, Behavior and Evolution 25, 1–80.

ganglia circuits to motor cortex, occulomotor cortex, anterior cingulate/medial orbitofrontal, lateral orbitofrontal, and dorsolateral regions in both species.

However, there are also possibly unique prefrontal–striatal connections from prefrontal granular regions. Wise (2008) notes that if the granular prefrontal cortex is unique, it likely projects to parts of the striatum that other species also lack, possibly found in the more dorsal striatal regions.

In sum, the definition of prefrontal cortex remains inconclusive as no single criterion will suffice. The best current definition is that the prefrontal cortex is the region in the cerebral cortex that includes the tissue that has projections from MD and/or amygdala and that has extensive projections to the basal ganglia and rest of the cerebral cortex. Given the extensive period of modification of cerebral regions in mammalian evolution, we should not be surprised that there is considerable variation in the details of prefrontal organization and function and that although many prefrontal regions are ubiquitous across mammals, there are some uniquely primate regions as well.

Why Is There a Prefrontal Cortex?

A key concept in answering this question is to remember that it is behavior, not the cortex that is selected. Hence, the question becomes "What behaviors were selected that led to the development of the prefrontal cortex?" Warren and Kolb (1978) argued that although the details of behavior vary, in general mammals must solve many of the same problems in their daily lives. For example, all mammals detect and interpret sensory stimuli, relate this information to past experience, and generate behavioral strategies. Although the details of what the animals do vary with species and likely have been selected to promote survival in a specific niche (i.e., species-typical behaviors), there are general behavioral capacities demonstrable in all

Figure 2 The prefrontal cortex in the human, with cytoarchitectonic areas numbered according to Brodmann's map.

mammalian species and could be designated as class-common behaviors.

But what is the class-common function(s) of the prefrontal cortex? This is a difficult question, but a review of theories of frontal-lobe function produces a common theme that the prefrontal cortex is involved in the temporal organization of behavior (e.g., Fuster, 1998; Goldman-Rakic, 1987). The general idea is that the prefrontal cortex supports cognitive functions that are necessary to organize behavior in time and in context. The temporal/contextual control of behavior requires at least six components. First, there must be an ongoing record of sensory experience that has occurred recently. This allows behavior to be disconnected from ongoing sensory stimulation and related to other stimulation that may have occurred previously. Second, there must be an ongoing record of what movements are being produced by the brain at any given moment, a record known as reafference. Reafference allows the prefrontal cortex to modify ongoing behavior in response to changes in the environment. Third, there must be selection of incoming experiential information, a process often referred to

as attention. The importance of particular sensory information obviously varies depending upon the environmental demands at any given moment. Fourth, there must be inhibition of some motor impulses and excitation of others to produce appropriate behavioral sequences. Fifth, behavior must be flexible with respect to both internal and external environments. It is one of the characteristics of mammals that we are able to adapt behavioral patterns to changing contexts. The importance of context-dependent behavior is clear in the complex social interactions of mammals. The make-up of the social group at any given time dictates the behavior of each animal. Species as diverse as apes and horses, for example, have a clear pecking order but the details of this social order varies with the precise grouping. Given the presence and position of certain animals a given ape (or horse) may be bold and relaxed whereas the presence of a single additional ape may lead to the same animal being quiet and nervous. It is likely no accident that the prefrontal cortex has grown so large in primates, an order known to be highly social. Sixth, there must be an ongoing monitoring or the consequences of behavior. If reward is associated with a particular set of behaviors, but not with another, then the association between movements and consequences needs to be made.

The Connectome and the Prefrontal Cortex

Continuing research into charting human brain connectivity and the connectome reveals that frontal-lobe regions are central to many cortical networks (van Essen and Ugurbil, 2012; www.humanconnectome.org). The most-studied network, called the brain's *default network*, links a set of far-flung brain regions active in participants who are resting rather than engaged in specific cognitive tasks (Buckner, 2013). Buckner emphasizes, however, that 'default network' is a misnomer, because this network is also active during such directed tasks as thinking about one's past (autobiographical memory), thinking about the future, or when the mind is 'wandering.'

A related salience network is seen in correlated activity among the anterior cingulate cortex, supplementary motor cortex, and anterior insular cortex. Bonnelle et al. (2012) suggest that the salience network is most active when a behavioral change is needed and that it operates to modulate other networks' activities. For example, if the salience network is not functioning properly, the default network shows excessive activity, leading to lapses in attention.

The prefrontal cortex is also a major participant in many cortical networks involved in emotional behaviors (e.g., Roy et al., 2012). The ventromedial prefrontal region plays an especially active role in these networks, and mood disorders result from abnormal activity in these systems (Price and Drevets, 2012).

Intelligence and the Frontal Lobes

The large evolutionary expansion of the prefrontal cortex suggests that increased human intelligence relative to other primates is related to prefrontal size. But until recently, the general consensus held that intelligence does not reside in the frontal lobes (e.g., Hebb, 1949), because large frontal injuries, including frontal lobotomies, have little effect on intelligence as measured by standard intelligence tests. Yet for more than a century psychologists have searched for other measures of intelligence, so perhaps intelligence and the frontal lobe can be related to measurements other than IQ score.

Nearly a century ago, Spearman (1927) proposed that some general factor (the *g* factor) contributes to all cognitive activity. Although his idea has been widely criticized, in fact, a near-universal positive correlation among cognitive tests suggests that, indeed, something like *g* does exist. The best single tests of *g* usually involve problem-solving tasks, which engage fluid intelligence, the ability to see abstract relationships and draw logical inferences. Fluid intelligence can be contrasted with crystalized intelligence, the ability to retain and use knowledge acquired through prior learning and past experience, which is highly related to Weschler IQ score.

Brain imaging studies link tests of fluid intelligence to a characteristic pattern of activity, both in dorsolateral and medial prefrontal cortex and in posterior parietal cortex. Key structures include posterior parietal and prefrontal regions, which the researchers propose, are related to processes of integration and abstraction (posterior parietal) and problem solving, evaluation, and hypothesis testing (prefrontal) (see reviews by Colom et al., 2010; Deary et al., 2010).

Wise (2008) argued that the prefrontal granular cortex is the location of this expanded intellectual capacity and it functions to store knowledge about how to behave under a wide range of nonroutine and complicated circumstances, all of which require attention to our actions and the diverse behavioral contexts encountered over a lifetime. He argues further that this expanded capacity in primates confers only a subtle advantage, but it has enormous consequences. Specifically, he proposes that when we primates recognize a rare risk in a complex pattern of events or an outstanding opportunity knocks, we have advantage because we are so good at knowing what to do and what is likely to happen in the event.

Passingham and Wise (2012) propose that the unique primate capacity makes a qualitative leap in humans. They argue that new prefrontal and posterior parietal areas emerged during the evolution of anthropoid apes, eventually leading to disproportionately large prefrontal and parietal regions in the modern human brain, which laid the groundwork for prefrontal–parietal networks for the expansion of fluid intelligence (general problem solving) in humans (Genovesio et al., 2014). Genovesio et al. argue that as our ancestors' brains enlarged, larger metabolic demands placed a premium on identifying productive foraging locations that might differ in food quality, volume, and danger in getting to the food. According to this hypothesis, foraging strategies that supported reduced risk taking and hominid survival also selected for the superior problem-solving capacities that evolved in humans and thus increased our intelligence. The risk-taking behavior frontal-lobe patients display illustrates what happens when the newly evolved frontal system dysfunctions. Further, the new problem-solving capacities would not be tapped by standard IQ tests, which is consistent with the clinical observations of frontal-lobe patients.

Symptoms of Prefrontal Cortex Injury

There are five general categories of symptoms associated with disease of the prefrontal cortex. We do not mean to imply that the brain respects these categories but rather that the categories provide a conceptual framework within which to consider the symptoms.

Disturbances of Motor Function

In a classic paper, Karl Lashley (1960) asked how movements are put together in a particular order. How is it, he asked, that a violinist can play an arpeggio so quickly and flawlessly? Clearly, each note is not 'thought of' separately. And how is it that, in a tennis game, a player can move much too fast to have considered each movement by itself? The selection and programming of movements is impaired by injury to both the supplementary motor cortex (*see* Premotor Cortex) and prefrontal cortex. For example, patients with prefrontal lesions have deficits in the copying of sequences of hand and limb or facial movements. Although the patients can make the required movements, they have difficulty in placing them in the correct order.

Another form of movement disorder is in the generation of facial and tongue movements in speech. Patients with injury to Broca's area and related prefrontal regions on the left are impaired at the production of speech and, as well, have deficits in using verbs and producing appropriate grammar. Verbs describe movements and grammar requires the correct sequencing of words.

Loss of Divergent Thinking

As noted earlier, frontal-lobe lesions do not affect performance on standard IQ tests, but they do affect performance on tests of problem solving. Problem solving requires an ability that has been referred to as divergent thinking by Guilford (1967). He noted that traditional intelligence tests appear to measure what can be called convergent thinking – that there is just one correct answer to each question. Definitions of words, questions of fact, arithmetic problems, puzzles, and block designs all require single correct answers that are easily scored. In contrast, divergent thinking requires the generation of multiple answers to a single question rather than a single correct answer. An example is asking for a list of the possible uses for a brick.

Frontal-lobe injury interferes with the intelligence required by divergent thinking. One example is reduced behavioral spontaneity. Frontal-lobe patients are unable to generate many answers to questions such as "write down as many words starting with 'S' as you can think of" or "make as many different doodles as you can think of" in 5 min. This deficit is not just seen in paper and pencil tests but in other tests as well, such as in a test requiring patients to "make as many different movements of the hand and arm as you can think of in 5 minutes"

Patients with frontal-lobe lesions are also especially impaired at developing novel cognitive plans or strategies for solving problems. This is especially true when they encounter a novel challenge where well-practiced strategies will not suffice. For example, when patients are asked questions that require reasoning based on general knowledge and for which no immediate strategy is obvious, frontal-lobe patients perform poorly and often gave bizarre responses.

Environmental Control of Behavior

Perhaps frontal-lobe patients' most commonly observed trait is difficulty in using environmental cues (feedback) to regulate or change their behavior. This difficulty manifests itself in myriad ways. For example, patients consistently perseverate on a variety of test situations, particularly those with changing demands. The best example is observed in the Wisconsin Card Sorting Test, a standard clinical test of frontal-lobe injury. In this test, a subject is presented with four stimulus cards bearing designs that differ in color, form, and number of elements. The subject's task is to sort the cards into piles in front of one or another of the stimulus cards. The only help given the subject is to be told whether the choice is correct or incorrect.

The test works on the following principle: the correct solution is, first, color; when the subject has figured out this solution, without warning the correct solution then becomes form. The subject must now inhibit classifying the cards on the basis of color and shift to form. When the subject has succeeded at selecting by form, the correct solution again changes unexpectedly, this time to the number of elements. It will later become color again, and so on.

Shifting response strategies is particularly difficult for people with frontal lesions. They may continue responding to the original stimulus (color) for as many as 100 cards until testing is terminated. Throughout this period, they may comment that they know that color is no longer correct. They nevertheless continue to sort on the basis of color. One person stated (correctly): "Form is probably the correct solution now so this [sorting to color] will be wrong, and this will be wrong, and wrong again."

Temporal Memory

Temporal memory (or working memory) deficits were the first to be demonstrated quantitatively in both laboratory animals and humans, and these deficits have strongly influenced many theories of prefrontal function (e.g., Fuster, 1998; Goldman-Rakic, 1987). The first demonstrations were seen in a test known as delayed response. If the location of reward is signaled by a cue (such as a light), both human and nonhuman laboratory animals cannot remember where the cue was after only a few seconds. Although this was initially interpreted as evidence of a short-term memory deficit, it can equally be attributed to a disorder of attention (see Wise, 2008).

Emotion and Social Behavior

Changes in effect and social behavior are obvious and striking effect of prefrontal cortex damage. The most publicized example of personality change subsequent to frontal-lobe lesions is that of Phineas Gage, first reported by John Harlow in 1868. Gage was a dynamite worker who survived an explosion that blasted an iron tamping bar through the front of his head. The bar, was about 1 m long and 3 cm wide at its widest point.

After the accident, Gage's behavior changed completely. He had been of average intelligence and was "energetic and persistent in executing all of his plans of operation" according to Harlow, but afterward he was "fitful, irreverent, indulging at times in the grossest profanity, manifesting but little deference to his fellows, impatient of restraint or advice when it conflicts with his desires, at times pertinaciously obstinate, yet capricious and vacillating, devising many plans of operation, which are no sooner arranged than they are abandoned in turn for others appearing more feasible."

Disorders Affecting the Frontal Lobe

Many people with psychiatric or neurological disorders present symptoms characteristic of frontal-lobe injury. Disturbance of frontal function likely contributes significantly to the behavioral symptoms of each disease. In addition, chronic stress alters prefrontal neurons in ways that affect some memory and behavioral functions.

In schizophrenia, there is an abnormality in the mesolimbic dopamine projection that terminates largely in the prefrontal cortex, a decrease in blood flow to the frontal lobes, and possible frontal-lobe atrophy. Schizophrenia patients perform poorly on all tests of frontal-lobe function, but they perform normally on tests of parietal-lobe function. Similarly, patients with Korsakoff's syndrome, a metabolic disorder of the central nervous system often associated with chronic alcoholism that results in degeneration of MD, also perform poorly on tests of prefrontal function.

Addictive drugs change the structure of neurons in both the orbitofrontal and the medial prefrontal regions in rats (for a review, see Robinson and Kolb, 2004). Drug addiction is likely related to abnormalities in prefrontal structure and function that are associated with the maladaptive decision-making characteristic of addictive behavior.

Prolonged stress is correlated with functionally significant changes in the structure of neurons in the prefrontal cortex that affect temporal memory and goal-directed behaviors (see review by McEwen and Morrison, 2013). Laboratory animal studies have shown that chronic stress in male rats reduces synaptic space in neurons in the medal prefrontal cortex but increases synaptic space in the orbitofrontal cortex. In contrast, similar stress in female rats produces the opposite effect in medial PFC regions. In young adult rats these changes are at least partially reversible with periods of reduced stress, but aged animals show no such recovery. We can speculate that age-related decline in cognitive abilities could partly reflect the chronic effects of stress throughout a lifetime.

Abstract

The prefrontal cortex (PFC) is the anterior-most portion of the cerebrum and functions to plan and direct behavior in varying contexts over time. It supports important socioemotional and cognitive skills, also known as executive function, that are associated with both academic achievement and life success. The PFC is comprised of many subareas that work together and with other cortical and subcortical regions of the brain to produce the complex cognitive and emotional capabilities associated with human behavior. The PFC is the last brain region to mature and development in this area proceeds into the fourth decade of life. The slow timeline for development of the PFC makes it more sensitive to environmental influences. This allows the acquisition of convention learning through experience but leaves the PFC vulnerable to external insults that may result in suboptimal development and neuropsychiatric disease.

Introduction

The prefrontal cortex (PFC) is the anterior area of the frontal cortex and it accounts for approximately 25–30% of the cortical mantle. It is the association cortex of the frontal lobe and is located anterior to the premotor and motor cortices. The major anatomical features of the PFC are large pyramidal neurons in layer III and granularity of layer IV although the granularity is less pronounced in rodents than in humans, nonhuman primates, and carnivores (Kostovic et al., 2008). Although a universally accepted definition of PFC does not exist, it has historically been thought that input from the medial dorsal nucleus (MD) of the thalamus to rostral regions of the frontal cortex is a unifying feature. The PFC receives input from all other cortical areas and its main function is to plan and direct behavior of all types (i.e., motor, cognitive, emotional, and social) across time. In fact, the PFC supports what is termed 'executive function (EF)' and thus is considered the executive of the brain. EF refers to important socioemotional and cognitive skills that are known to be highly correlated with both academic and life success. EF is blanket term that is considered to include creativity, self-regulation, organization and planning, problem solving, and working memory. The PFC has a protracted developmental timeline that starts in the prenatal period and finishes in the fourth decade of life when myelination is complete (Kolb et al., 2012). It is the last area of the brain to mature and as a result is sensitive to a variety of experiences that shape the underpinnings of complex cognitive and emotional capabilities. The PFC's prolonged period of maturation also makes it more sensitive to adverse experiences that can result in abnormal PFC development (often manifested as neuropsychiatric disorders.)

Subregions of the PFC

The PFC is considered multimodal association cortex that receives and integrates highly processed information from sensory association areas (granular cortex) as well as information from limbic areas (agranular and dysgranular cortex). The PFC is not a homogeneous area and as such is generally divided into subregions using location, cytoarchitecture, and connectivity as defining features (*see* Prefrontal Cortex for a figure showing prefrontal cortical regions). The PFC can be divided into three major subregions:

1. *Lateral prefrontal cortex* (*LPFC*), Brodmann's areas 9 and 46, mainly make reciprocal connections with the posterior parietal areas and the superior temporal sulcus. The dorsolateral cortex has extensive connections with regions to which the posterior parietal cortex also projects, including the cingulate cortex, basal ganglia, and superior colliculus.
2. *Orbitofrontal cortex* (*OFC*), areas 47 and lateral portions of 11, 12, and 13, gain input from all sensory modalities. The OFC's main cortical afferents project from the temporal lobe, including the auditory regions of the superior temporal gyrus, the visual regions of the inferotemporal cortex (area TE), S2 (somatosensory area 43), gustatory cortex in the insula, and olfactory regions of the pyriform cortex.
3. *Medial prefrontal cortex* (*MPFC*), areas 10, 14, and 25, as well as medial parts of areas 11, 12, and 13, and the anterior part of 32, receives cortical connections from the dorsolateral PFC (DLPFC), posterior cingulate cortex, and medial temporal cortex.

In addition to these three prefrontal regions, another region called the anterior cingulate cortex, is closely associated with the PFC. This region includes Brodmann's area 24 and part of 32 and makes extensive bidirectional connections with motor, premotor, prefrontal, and insular cortex.

Function and Connectivity of PFC Subregions

The subregions of the PFC are highly interconnected, which suggests that prefrontal functions are subserved by multiple areas of the PFC. The PFC has reciprocal connections with sensory cortical areas that may be a result of its use of integrated sensory information to guide top-down attentional demands. The PFC is also highly connected to the parietal and temporal lobes of the brain, which support spatial and memory

processes. Finally, the PFC is highly interconnected with subcortical structures including the hippocampus, basal ganglia, thalamus, hypothalamus, and the amygdala. Connections of some subregions of the PFC to limbic areas may reflect the use of affective information to guide behavior based on social information and environmental contingencies.

Medial Prefrontal Cortex

The MPFC is involved in the processing and integration of affective and social information (Grossmann, 2013). It is also involved in memory and decision-making. Based on the myriad of functions that seem to be supported by the MPFC, Euston et al. (2012) propose that the MPFC with support from the hippocampus is responsible for recalling the best course of action or emotional response to specific events in specific contexts.

Ventral Areas

The ventromedial portion of the MPFC functions to regulate emotional responses in a manner consistent with changing environmental contexts. It has diverse neural connections that include sensory input from all modalities and output to areas that contribute to emotional regulation and expression (e.g., amygdala, hypothalamus, ventral tegmental area, and medial temporal cortex). It integrates social and affective information and thus contributes to a wide range of social cognitive abilities. The ventromedial PFC has recently been shown to be critical in the regulation of amygdala activity (Motzkin et al., 2014). The rostral portion of the PFC, while the largest subarea of the PFC is perhaps the least well understood. It is connected to areas in the frontal, parietal, and temporal lobes (Gonen-Yaacovi et al., 2010) and has been shown to be activated by pleasant touch through its connections with reward-related regions. The rostral PFC has low cell density that may reflect more space available for intrinsic and extrinsic connections and it has an extraordinarily high number of dendritic spines per cell suggestive of an important role in integration or coordination of incoming information. It has been proposed that the rostral PFC supports prospective memory or the ability to carry out an intentional act on the basis of previously acquired information and mentalizing (Theory of Mind) or development of the understanding of mental states in both self and others (Dumontheil et al., 2008). The rostral PFC has also been implicated in higher order decision-making associated with exploitation of available resources (Wunderlich et al., 2009).

Dorsal Areas

The dorsal MPFC is recognized to play a role in decision-making, conflict monitoring, and reward-guided learning (Botvinick, 2007; Rushworth and Behrens, 2008). It receives input from the insula, limbic regions, and sensory association cortices (Cavada and Reinoso-Suarez, 1985), and higher order motor areas in the frontal lobe (Matsuzaka et al., 2012). Recently, the dorsomedial PFC has been additionally implicated in understanding mental states in others and empathy (Waytz et al., 2012; Kang et al., 2013) whereas the rostral PFC shows greater activation when understanding the mental state of self (Kang et al., 2013; D'Argembeau, 2013).

Lateral Prefrontal Cortex

The LPFC is primarily involved in the processes of cognitive control and memory and is strongly connected to the temporal cortex (Takahashi et al., 2006).

Ventral Areas

The ventrolateral regions of the PFC are involved in active retrieval and selection of information (first-order executive processes (Tanji and Hoshi, 2008)). In addition, the right ventrolateral PFC has been identified as active in tasks of self-control under a variety of conditions including response inhibition, thought suppression, and delayed gratification (Cohen and Lieberman, 2010). It has connections with the amygdala, superior temporal polysensory area, and auditory areas.

Dorsal Areas

The DLPFC is involved in motor planning and organization and as such has connections with the basal ganglia and ventral anterior nucleus of the thalamus (Rektorova et al., 2008; Morris et al., 2014). It is also commonly associated with working memory processes (Cieslik et al., 2013). It has connectivity with the dorsal (how) pathway and the ventral (what) pathway of the visual system as well as the posterior parietal cortex (Olson and Luciana, 2008; O'Reilly, 2010). It also has connectivity with the OFC and plays a contributory role to intelligence and higher order thought processes (Barbey et al., 2012).

Ontogenetic Development of the PFC

Prenatal Development

Although neurons destined for the PFC are produced in the ventricular zone from neuroepithelial cells at 7 weeks postconception, the cytoarchitectonic hallmarks of the PFC are not visible until 36 weeks postconception. Afferents from monaminergic (dopamine and serotonin) areas of the brain stem arrive in the frontal areas of the cortex at approximately 9 weeks postconception whereas acetylcholine innervation of the frontal areas does not appear until about 13 weeks postconception. Fibers arising from the MD of the thalamus invade the cortical plate between 24 and 28 weeks postconception and callosal connections arise approximately 32 weeks postconception and are refined through elimination into the postnatal period of life (Kostovic et al., 2008).

Postnatal Development

In the neonatal period there is rapid formation of dendritic spines in the PFC with the number peaking at about 2.5–4 years, depending upon the region and cortical layer (Petanjek et al., 2011). Spine development occurs in association with the acquisition and refinement of language and related cognitive processes. The process of synaptogenesis occurs largely as a result of intense interactions with environment and implicates experience as an important factor in the stabilization and pruning of PFC synapses (Nelson et al., 2000). A recent study on synaptic spine formation in the PFC over the lifespan has confirmed that spine density in childhood

is two- to threefold higher than the spine density observed in adults and shows a downward decline during puberty, which continues into the third decade of life (Petanjek et al., 2011).

Giedd et al. (1999) showed that in frontal areas, gray matter volume peaks between 11 and 13 years followed by a prolonged period where gray matter volume is reduced. Although decreases in gray matter volume have commonly been attributed to synaptic pruning, Dumontheil et al. (2008) caution that such changes may additionally arise from increases in myelination in the PFC areas during this period.

When brain growth is assessed using a 'distance from center' measure to examine the radial expansion of exterior cortical surface, the rostral PFC shows one of the highest rates of brain growth between the ages of 5 and 11 years and continues to show growth throughout the period of adolescence (Sowell et al., 2004). It has been proposed that the prolonged development of this PFC area along with its unique anatomical characteristics support the notion that the function of the rostral PFC is to support the cognitive behavior that uniquely distinguishes humans from other species (Dumontheil et al., 2008).

Myelination, which speeds the rate of information flow between neurons, begins largely in the postnatal period for the PFC and continues into the fourth decade of life. While it is tempting to suppose that the maturational timeline for myelination of the PFC is genetically controlled there is clear evidence that environmental influences play an integral role in this process. For example, studies of pianists show that intensive training that occurs over many years is associated with increased myelination (Bengtsson et al., 2005).

Not surprisingly the subregions of the PFC have different rates of maturation. The most protracted development of the PFC appears in the rostral PFC and the DLPFC (Olson and Luciana, 2008).

Sex differences also exist in PFC development on the basis of maturation and are area dependent. For example, the ventromedial PFC appears to develop the earliest among the areas of the PFC and this maturation occurs earlier in males than in females. Conversely, the myelination process that requires decades to complete in the rostral PFC is finished earlier in females than in males.

Functional Development of PFC

When considering the development of the brain, the concept of 'sensitive periods' or periods of time when experiences have stronger influences functional and anatomical outcomes comes in to play. In sensory brain areas the sensitive periods largely occur in the first year of life but in the PFC the sensitive period appears to extend into late childhood or early adolescence. It has been proposed (Thompson-Schill et al., 2009) that delayed maturation of PFC, at a cost of functional performance in infancy and early childhood, is advantageous for human learning. The theory outlined by Thompson-Schill and colleagues makes a case for 'cognition without control.' The basic tenet of this theory is an immature brain is better positioned to master cultural and linguistic conventions, or convention learning. As an example, the authors highlight the mental processes associated with 'creativity.' They note that when faced with a challenge to create new uses for a familiar object, adults often struggle, in part because they have a wealth of experiences with the object that shape their expectations about its use. Conversely, young children are not hindered by this 'functional fixedness' and are able to create a myriad of uses for such an object. Children are also better at language acquisition than adults and this talent arises as a benefit of an immature PFC. A mature PFC provides adults with the ability to think flexibly and to capably use contextual information to optimize behavioral output or performance. Thompson-Schill and colleagues argue that the PFC optimizes performance of an individual and if it were to mature earlier, broader aspects of learning subserved by subcortical areas would be preempted.

PFC Function in Infants

Despite the prolonged period of maturation of the PFC in humans, significant changes occur in the first year of life and function to support cognitive advances seen in infants at this time. Infants are born with the behavioral biases to attend to certain stimuli in their environment, i.e., faces and voices. These biases may provide the foundation on which social cognition is built. Using near infrared spectroscopy or NIRS researchers discovered that newborns show greater activation in the MPFC to their mother reading a story using infant-directed speech versus adult-directed speech (Saito, 2007). Infants at 4–13 months of age when tested with a strange female voice and their mother's voice only showed activation of the MPFC when their mother's voice was heard (Naoi et al., 2012). This work, along with behavioral work shows that by 7–9 months of age infants show strong preferences for their primary caregiver and this is supported through changes in PFC function. Further studies using NIRS showed a simple smile that was preceded by eye contact activates the PFC in 4-month-old babies (Grossmann et al., 2008) and 9- to 12-month-old infants showed significantly greater activation of the MPFC to their smiling mother when compared to a stranger (Minagawa-Kawai et al., 2009). Interestingly, mothers of the babies exhibited a similar PFC response when looking at their own infants smiling. Grossmann et al. (2013) used NIRS to demonstrate that 5-month-old infants when gazing at an object in their environment were able to detect when their adult social partners followed their gaze to that object. The detection was demonstrated by activation in the left PFC. Using NIRS, Kida and Shinohara (2013) demonstrated that 10-month-old babies show activation of the rostral PFC, similar to adults, when touching velvet but this response is absent in 3- and 6-month-old babies. This suggests that maturation of the rostral PFC is required to process activation in the tactile affective system and the critical point of maturation is between the sixth and tenth postnatal month. Neuropsychological tests on infants and children have demonstrated that working memory or the ability to hold important information in mind begins to develop at about 8 months of age (Diamond, 1985). This suggests that the DLPFC, the area supporting this ability, is beginning to show maturational changes as well.

PFC Function in Children

Children as young as 1 year of age begin to show signs of attentional control, an EF associated with control of

emotional behavior by the ventromedial PFC. In contrast, the development of metacognitive forms of EF (planning and verbal fluency) supported by the DLPFC does not begin until about 3 years of age (Ardila, 2013). Perlman et al. (2014) used NIRS in 3- to 5-year-old children to identify the PFC locations activated during 'winning' and 'frustration.' Their results show that winning activated the MPFC whereas the LPFC was activated during frustration. A recent study of the maturation of planning abilities in girls and boys was conducted on 4- and 5-year-olds with a re-test interval of 1 year (Unterrainer et al., 2013). The Tower of London task was employed to assess how planning strategies matured in these children over the course of 1 year. It was shown that girls mature in advance of boys in their development of planning at this age and this appeared to be related to differences in maturational rates of the DLPFC in girls and boys. Takeuchi et al. (2013) examined the effects of TV viewing on brain structure in children using structural magnetic resonance imaging (MRI). They gathered preexperimental data from children between the ages of 5 and 18 years and then re-studied them 2 years later. They demonstrated that duration of TV viewing was positively correlated with both gray matter and white matter volume in the rostral PFC and MPFC areas. They also confirmed that duration of TV viewing was negatively correlated with IQ in these children. This study demonstrates the powerful impact that environment wields over maturational processes in the PFC.

PFC Function in Adolescence

Adolescence is defined as the transitional period of life that spans late childhood to adulthood. Early adolescence is characterized by puberty, which is associated with surging gonadal hormones. Interestingly, these gonadal hormones confer a high degree of neuroplasticity in certain brain areas and one area affected is the PFC. During adolescence the PFC undergoes extensive reorganization and it is particularly sensitive to environmental influences. The involvement of epigenetics in the mechanisms underlying the dynamic changes in the PFC at this age has been largely understudied. Epigenetic mechanisms are highly responsive to the environment and as such may also contribute to the vulnerability of the PFC to negative experience during adolescence (Morrison et al., 2014).

The emergence of self-consciousness was examined in child, adolescent, and adult populations using fMRI (Somerville et al., 2013). Participants viewed cues that lead them to believe that a peer was actively watching them and this caused increases in autonomic arousal that was particularly prevalent in the adolescent group. This behavioral pattern was accompanied by emergent striatal and MPFC connectivity during adolescence that has been thought to promote social evaluation of contexts.

In a study aimed at evaluating the development of affective theory of mind, children of age 12–14 years and adults (19–25 years) were recruited to undergo fMRI while evaluating video clips of actors displaying various affective mental states. The ventromedial PFC showed stronger activation in adolescents than in adults while viewing the videos, a finding that suggests this area may be involved in the development of affective theory of mind processing in adolescents.

Recently, a longitudinal study (participants aged 9–23 years) was conducted to examine the brain regions that support inhibitory control (Ordaz et al., 2013). fMRI data from over 100 participants were gathered and specific brain regions within circuits that support motor response control, executive control, and error processing were studied. The data revealed that mean growth curves of activation in motor control regions did not change with age, executive control regions showed decreased activation with age until adolescence, and processing activation of the dorsomedial PFC and anterior cingulate increased into adulthood. The results suggest that these processes possess distinct maturational timelines that contribute to the unique behaviors exhibited by teens.

Risk-taking is a behavioral trait that is commonly exhibited by adolescents. It has been proposed that poor executive control and delayed PFC maturation contribute to risk-taking behavior. A review of MRI, behavioral studies, and epidemiological studies suggest that incentive motivation arising from limbic areas shows a substantial increase from childhood to adolescence and then declines. Immature PFC function at the same time may make this motivation hard to subdue and thus risk-taking increases (Luciana, 2013).

Environmental Influences on PFC Development

Although brain development proceeds along a basic template that is genetically determined, it is clear that experiential factors contribute to and alter developmental trajectories and behavioral outcomes. Two characteristics of PFC organization are important for advancing our understanding of how environment has such a dynamic impact on this cortical area. First, dendritic spine density, a proxy for excitatory synapses, is two- to threefold higher in the PFC of children than in adults. Second, the overproduction of dendritic spines in development is highest and the rate of synapse elimination is lowest in the PFC. Using rodent models to study behavioral changes mediated by anatomical changes in the PFC, a wide variety of environmental factors (experiences) have been identified that change the development of the circuitry in the PFC. These include sensorimotor experience, exposure to stress, parent–infant relationships, peer–peer relationships, and exposure to psychoactive drugs (Kolb et al., 2012). Interestingly, the timing of the experience (age at exposure), the sex of the subject, and previous environmental exposures all contribute to the impact of the experience on the behavioral and anatomical outcomes. It is clear that maternal experience during pregnancy can influence behavior and brain development in the offspring and it has recently been shown that the same is true for father experience in the preconception period (Mychasiuk et al., 2012, 2013).

Neurodevelopmental Disorders and the PFC

Attention Deficit Hyperactivity Disorder

In a recent experiment, Shaw et al. (2007) used MRI to examine cortical thickness in children ranging in age from

preschoolers to young adults. Participants were scanned at least twice in 3-year intervals. The researchers demonstrated that children with attention deficit hyperactivity disorder (ADHD) show normal maturation of the brain but the maturational timeline lagged behind children without the disorder by about 3 years. Development of the MPFC was delayed by up to 5 years in youth with ADHD compared to undiagnosed controls. The motor cortex was the only area examined that showed accelerated development in the ADHD-affected children. This mismatch in developmental timelines of the PFC and motor cortex may account for inattention, restlessness, and fidgeting in affected children.

Autism

In 2002, Carper and colleagues conducted an MRI study on 2- to 11-year-old children diagnosed with autism. Their data revealed an increase in cortical thickness in the frontal lobe of autistic children compared to controls with the biggest differences observed in 2- and 3-year olds. In a postmortem study of PFC tissue derived from autistic individuals and controls, Courchesne et al. (2011) discovered that the tissue derived from autistic individuals (aged 2–16 years) had 79% more cells in the DLPFC and 29% more cells in the MPFC compared to normally developing controls. These results suggest that the autism phenotype may result from exuberant growth in the PFC and a failure to prune unnecessary cells and connections.

Schizophrenia

Over the past two decades, schizophrenia has increasingly been regarded as a neurodevelopmental disorder. It was previously believed that negative events in the prenatal period of life derailed brain function two decades later in patients affected with schizophrenia. Now that PFC has been shown to undergo an extended period of development, the notion that negative events in postnatal life, childhood, and early adolescence may contribute to the disease is gaining more acceptance. In late adolescence or early adulthood when a diagnosis of schizophrenia is made, fMRI studies show abnormal PFC activation during performance of working memory tasks. Specifically, patients show greater activation of PFC in association with reduced performance on working memory tasks (Callicott et al., 2000). What is not clear is how these changes arise. In 2013, Catts and colleagues published work that suggested the best way to understand the neuropathology associated with schizophrenia is to better understand the processes underlying normal brain development.

Metaplasticity and the PFC

The experiences an individual has during the period of PFC development have the potential to alter neuroplasticity in this area. This altered circuitry then responds differently to experiences that occur later in life, a phenomenon called metaplasticity. Consider the following example. Using a rodent model, the effect of cognitive training on a two-way active avoidance (TWA) paradigm during infancy was examined on later cognitive performance after training in adulthood. This was compared to pretraining on the TWA followed by training in adulthood (Bock et al., 2014). The authors were surprised to discover that the infant training improved avoidance learning in adulthood even though the infant rats were unable to learn a successful avoidance strategy. In addition, training in infancy was more effective than pretraining on the same task in adulthood. These results support the notion that infant cognitive training alters developmental organization and primes PFC neuronal circuits for adult learning.

Training EF to Support Academic Achievement and Life Success

One of the most intriguing aspects of PFC development in childhood is the notion that training can enhance EF and improvements in EF will lead to better success in school and in life. A number of tests of EF have been developed to assess this ability in children as young as two in order to determine if remediation is warranted so it can be delivered in a timely fashion such that a child starting kindergarten will have the necessary EF skills in place to ensure better academic success. This notion is appealing to researchers, educators, and parents alike and could make an important difference in life outcomes of children. A word of caution comes to mind based on the theory proposed by Thompson-Schill and colleagues (discussed above).

If delayed maturation of the PFC is truly a benefit for learning in the developing brain, will earlier maturation truncate learning possibilities and force a premature emphasis on optimized performance of brain function without the necessary underpinnings of convention learning?

Abstract

In this article, the notion of 'prehistoric art' is shown to be a difficult one, with many implications and problems, and it is suggested that the term could be replaced by 'archaeological arts.' Several issues are raised for the study of prehistoric arts: the problems of (differential) preservation, the importance of archaeological context, the utility of materials science, and the techniques of chronometric dating. Among the major research questions in this field, two questions are highlighted: what are the 'origins' or the 'birth' of art, and how 'meaning' can be inferred from so-called objects of art.

People have been making objects, forms, and images that we consider to be 'art' for at least 35 000 years and perhaps even longer (Tribolo et al., 2006). Some claim that evidence of red ochre, as a kind of coloring material, indicates human engagement with artistic activities (such as body painting) for more than 200 000 years in Africa. Others have pointed to individual objects, dated to even earlier than that, which they are convinced were modified by ancient humans with an intent to represent something, suggesting that 'art' has long been a part of the cultural repertoire of humans, even of different biological species than we anatomically modern humans (Burdukiewicz, 2014; Zilhão, 2007). When most lay people learn that they are talking to an archaeologist, they inevitably ask, 'What is the most fantastic thing you have ever found?,' hoping we will be able to tell them about a gold decorated necklace, a carved figurine, or magnificent painted jar: they want to know about 'prehistoric art.'

The very term, 'prehistoric art,' is difficult to define (e.g., Palacio-Peréz, 2012). Technically speaking, it refers to the 'art' made by prehistoric peoples; that is, by people in those societies without, and usually before the development of, written texts. There have in recent times been human societies without writing systems (nonliterate) and with what might be called 'the arts,' but these are more likely to be what we call 'ethnographic arts' because they are still 'living' arts and can be described ethnographically. There are some problems with the way in which the term 'prehistory' is used, including the implication that, without writing systems, prehistoric groups have no history, and experienced little change. But we know this is not the case at all, and that there are myriad ways other than in writing by which 'history' is reckoned, transmitted, and experienced. Also, in relation to the idea of 'prehistoric art,' there are some archaeologically known societies, such as the Maya or Egyptians, who had writing systems, but whose 'arts' are sometimes referred to as prehistoric or, more often, as ancient art. In fact, it is perhaps better to think of the arts that we are interested in as the archaeological arts, rather than prehistoric ones. With such a term, we realize we are dealing with the art(s) from past human societies that we study by using the wide range of archaeological methods, theories, and techniques.

Then there is the term 'art,' which is itself notoriously difficult to define. Furthermore, it is a term that has had differing meanings even within the last two centuries of Western scholarship and culture. Since the nineteenth century, 'we' in the Western tradition have associated the term, 'art,' with aesthetics and aesthetically pleasing attributes; as something that is usually produced by specialists who are often considered to be gifted individuals with admirable degrees of creativity, and who are often separated from real-life, everyday activities. Our present-day notions of art include the idea that art is to be held in awe while, at the same time, the production and products of art are embedded in the capitalist system, with economic as well as cultural value; art objects function in their own domain, that of high culture and aesthetics.

However, all this is unlikely to be applicable to the art-making and art images and forms that we are concerned with in prehistoric and archaeological contexts. It is a well-known truism in anthropology that in most cultures which have been studied ethnographically, there is rarely a word, or even a concept, equivalent to our word and concept, 'art.' It is not really possible to try to separate out 'art' from other aspects of cultural life, such as art as something distinct from religion, social relations, and/or politics. Yet there are images, forms, and cultural practices in other cultural contexts, both ethnographic and archaeological, that we acknowledge unproblematically as 'art,' mostly because, if they were produced by our own culture, we would classify them readily as art: cave and rock paintings, sculpted figurines or statues, decorated bronze goblets, and the like.

Is there a better term: Visual culture? Material culture? Images? Representations? Material symbols? The term or label we use, such as 'art,' is not itself the real problem; what is more of an issue is that if we use such a term in our own sense, without recognizing its historical specificity, then what we mean by it is often left unexamined, and the analysis or interpretation of the phenomenon is led in certain directions because of the label. If what we have is 'art,' then there must be artists and aesthetic meanings. However, as Morphy (1999) has so eloquently noted: we need to develop a concept of art that 'neither distances the objects of other societies from Western cultures nor appropriates the object to European categories.'

Books that treat the topic of 'prehistoric art' as a single entity are rare; most book-length treatments are concerned with the art and imagery of specific regions (e.g., Keyser, 1992), time periods (e.g., Leroi-Gourhan, 1967; White, 2003), or in specific

media (Dowson, 1992; Clottes, 2002). In 1966, Powell authored an overview of prehistoric art, which was divided into four chapters: the art of the hunters, that of the cultivators, that of the metalworkers, and what he called the 'art of a barbarian nation,' referring to the Celts of Europe (Powell, 1966). His coverage was limited to Europe, and he treated each 'kind' of art by apparent categories of 'lifestyle,' but it is just as much a book about the 'progress' of art from the Paleolithic period (the hunters), through the Neolithic (the cultivators), the Bronze and Iron Ages (the metalworkers), to the 'archaic state' (Celts). As such, he presents a now-problematic evolutionist view, a view of 'progress' through different chronocultural periods. Indeed, for much of the nineteenth and twentieth century, the ethnographic (and archaeological) arts have been embedded in a progressivist notion (Errington, 1998); we used to talk unquestioningly of 'primitive art' (Price, 1989). Twenty-first century scholars, however, have become increasingly critical of the twentieth-century paradigm, instead demanding a broader conception of art that expands beyond Eurocentric boundaries placed on the concept (Moro-Abadía and González-Morales, 2008).

More recently, Bahn (1998) has authored an illustrated history of prehistoric art, but it is almost exclusively about 'rock art,' with a short chapter on 'body art' and one on 'objets d'art,' or portable art (items that could circulate). He returns again and again to a baseline of the Ice Age imagery of Europe, although this book is an important source for appreciating that rock art – paintings, engravings, and petroglyphs on rock surfaces, rock shelters, and in caves – is truly global in its distribution. Bahn's map of sites is a map of the world, while Powell's is one of Europe. This is indicative of a real shift of scope in our understanding and treatments of 'early art' and/or rock art from all times. As we will see later, the search for the earliest art has been one of the major preoccupations of many who study 'prehistoric art.'

How to Study Prehistoric Art

First, it is always important to recognize that the corpus of materials that we consider as 'prehistoric art' is certainly only a sample of what was made in the human past. There is always the problem of preservation, and that what we have in the present is only a sample of past artistic production. It is no coincidence that rock art, ceramic sculpture and decorated pots, metal objects, and images made out of ivory, bone, antler, shell, and beads of various sorts are some of the primary forms of prehistoric art. The wood, hide, basketry, cloth, netting and twining, feathers, and body art are rarely, if ever, preserved. If the arts of ethnographic groups are any indication, we have an impoverished archaeological sample of prehistoric visual and material culture.

But given the preservation of at least some portion of prehistoric artistic production, how do we then go about studying it? First, we need some theoretical or conceptual frameworks within which even to think about what the images and forms might be about, especially if we cannot directly apply our own notions of 'art,' artists, and aesthetics. Much of this has to come from related fields, such as the anthropology of art, the ethnographic arts, and art history. We need to draw on understandings of what visual and material representation is all about (e.g., Gombrich, 1961; Bryson, 1983), of symbolism (e.g., Geertz, 1983), and of humans as materialists and symbolists (Conkey, 1993; Gell, 1998); of how technology and materials are integral to the art forms (e.g., Lechtman, 1984), of style (Conkey and Hastorf, 1990); and of the social contexts and production of art (e.g., Wolff, 1981), and of the 'social life of things' (e.g., Appadurai, 1986). Studies of 'art' in ethnographic contexts (e.g., Morphy, 1991), general overviews of the anthropology of art (e.g., Layton, 1981), and ethnoarchaeological studies (*see* Ethnoarchaeology) provide important resources.

Second, we need to recognize the importance of the archaeological context of the so-called art forms, and we need to take context into consideration when we try to interpret or understand the meanings, uses, or even the making of the art. Do the preconceptions that female figurines – from about 7000 years ago from sites in such places as southeast Europe – are objects of worship and a female-centered world change when we recognize that some, if not many, of the figurines have been recovered from trash deposits, often broken? Are the Ice Age paintings of southwestern Europe found deep in caves, away from daylight, comparable to those found on daylit shelters? Is there a difference in the uses and meanings between objects found in everyday places and living sites, and those found in architectural structures that are so different in size, form, and location that they must be other-than-'houses'? The individual images and objects may well take their specific meanings from the locations where they were made and/or found, or from the other artifacts or structures with which they are associated.

We can use the most up-to-date techniques and methods, especially those of materials science, to make inferences about the images and objects: we can identify the sources of the raw materials, such as clay, stones, or pigments, which in turn can inform on trade, exchange, circulation of goods, and the social relations that effect such practices. We can identify different ways in which pigments were processed by Ice Age cave 'artists' in Europe (e.g., Clottes, 1993), and therefore suggest the social relationships that must have been obtained in order to have images in different sites made by the same pigment 'recipes.' We can show how certain fibers were used to apply pigment in Australian rock paintings (e.g., Cole and Watchman, 1992). We can infer the stages of manufacture of metal earspools (e.g., Lechtman, 1984) and how these stages resonate with other cultural principles and practices. We can use infrared photography to 'see' color and images that have long since faded away. We can use high-powered microscopic analysis to detect the precise strokes of a stone tool on the surface of a bone object; from such analyses have come the suggestion that lunar calendars may have been made at least 15 000 years ago (Marshack, 1991). These are just a few examples of how our increasingly sophisticated methods of materials science that are common in the analysis of other archaeological materials can be applied to the study of prehistoric art images and objects.

Both of these approaches – knowing the archaeological contexts of the art and the application of scientific techniques – have featured prominently in the increasing ability to date many objects and images (David et al., 2013; Pettitt and Pike,

2007; Tribolo et al., 2006). It has long been the case that objects that are found in stratigraphic context – that is, in the geological/archaeological layers of an archaeological site – can, if excavated and recorded carefully, be attributed to at least a relative date (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology). They can also be given more secure dates if other artifacts or materials in the same stratigraphic layer are suitable for some of the many techniques of archaeological or chronometric dating (*see* Archaeometry and Chronology, Stratigraphy, and Dating Methods in Archaeology). However, many art forms, such as rock art or objects that are unfortunately out of context, cannot be dated in this associative manner. Many of these images themselves cannot be dated at all, although recent advances have changed this somewhat. Earlier generations of scholars, for example, dated all the cave art of Europe or the varying rock art styles of Australia by means of stylistic criteria, often based on assumptions as to what 'ought' to be earlier image-making and what 'ought' to be later. At the same time, many researchers were reluctant even to consider the art as a subject worthy of archaeological study, primarily because it could not be dated (*see* Whitley and Loendorf, 1994).

That much art cannot be dated has, in combination with the fact that the interpretation of art is never straightforward (if only because it is the product of symbolic cultural practices that are not easily comprehended through the usual archaeological methods), led many archaeologists to dismiss art and images as viable archaeological data. This has been the case especially when it comes to objects and images from many thousands of years ago, where there are no real historic links between the archaeological 'cultures' and those known ethnohistorically or ethnographically, where there is no direct historical method that can be applied (*see* Archaeology, Theory in). Some have suggested that the recent explosion of interest in the global study of rock art is due, in part, to new dating methods that have allowed researchers to begin to date imagery with more security. For this genre of prehistoric art – rock art – the most important new technique has been the development of accelerator mass spectrometry carbon-14 dating, which can be done using a very minute sample of material, thus not destroying a painting or image, although it can only be used if there are organic materials in the pigments, such as charcoal (*see* Archaeometry).

Some Major Questions

At least two major questions come to mind when we sit down to address the subject of prehistoric art: first there is the question of the origins or the 'birth' of art; second, there is the challenging issue of how we can interpret the art and approach what it might mean. Until recently, it was thought that the cave paintings and other arts of the Upper Paleolithic period (*c*.30 000–10 000 years ago) in Europe comprised the 'first' art, even though images from ancient cultures had been found all over the globe (see Bahn, 1998 on the 'discovery' of prehistoric art). This was a compelling idea because there were many different caves with images and many other objects and art forms; because it seemed to be associated with the earliest evidence for anatomically modern humans – our own species, *Homo sapiens*; and because it was in Europe, which allowed for the idea of a continuous tradition of art – a crucial essence of what it means to be human – from deep prehistory up into the twenty-first century.

However, work during the last few decades of the twentieth century has undermined seriously the idea that there is any single 'birthplace' of art: both southern Africa (Tribolo et al., 2006) and Australia (David et al., 2013) have yielded rock art images that can be attributed to the same general time period as the European Paleolithic imagery. There are those who point to more isolated finds (see Bahn, 1998: 86–87), although many are debated hotly as being 'art' or intentional representations at even earlier dates. We now recognize that anatomically modern humans have a deeper history, perhaps as much as 200 000 years longer, than previously thought. However, the exact nature of the relationship between being anatomically modern and the appearance of representational and/or symbolic imagery is hardly resolved, but the fact that this kind of imagery appears in multiple locations, in varying forms and amounts, calls for a more contextual approach: what is it about life and social relations at these times that set a context within which 'art' – at least in more durable forms that have been preserved – became a part of cultural practices? While the search for 'the origins' of many phenomena in the human past is always a seductive question, as far as prehistoric art is concerned, it is now clear that there was no single 'center' for art-making, but that the preserved evidence around the globe attests the engagement of ancient humans with materials, images, and technologies (of working stone, of coloring materials, etc.) for cultural purposes that still elude us.

Thus, the final, but most difficult question is the interpretive one: how can we infer some (if any) of the meanings of prehistoric art? This question is both the most difficult and most complex question, and what everyone wants to know. Since all of archaeology is interpretive, while drawing on as much empirical evidence as possible, and since human behavior is so multivocal, with so many potential meanings and ambiguities, it is unlikely to expect a single answer, a single interpretation. Even in known or ethnographic contexts, the so-called meaning of art-making or of the art itself is ever-shifting, contextual, and multiple, dependent upon viewers, users, makers, and situations. Do we assume that prehistoric peoples were somehow 'simpler' and therefore a (simple) single account can suffice?

Despite the complexity of the challenge, there are some things that we can say about interpreting prehistoric art. In some instances, we can infer information clearly about clothing from human depictions, about activities as depicted in 'scenes,' preferred symbols or forms, and what kinds of object were traded or used in certain contexts. In other instances, we can advance general theories, such as the role of shamans in making images that derive from their visions (e.g., Lewis-Williams and Dowson, 1989; Turpin, 1994), such as the ways in which ritual landscapes were created with art forms and megaliths, such as the idea that some arts appear to be 'about' interpersonal social relations, whereas other arts appear to be 'about' maintaining the corporate entity (e.g., Layton, 1985). While we are unlikely ever to fix, with certainty, what a particular picture or object 'meant,' recent past decades have witnessed enormous gains, thanks to the application of scientific

techniques, the innovative and expanded theories for interpretation, and a more widespread recognition that the archaeological arts are just as crucial to our understanding of past societies as are other kinds of archaeological data.

Prejudice and Discrimination

Thomas F Pettigrew, University of California Santa Cruz, Santa Cruz, CA, USA

Abstract

Intensive research throughout the world has led to the broadening of social science conceptions of both intergroup prejudice and discrimination. Prejudice is now seen as occurring at varying levels of depth. In fact, it can be so subtle that people are often unaware of their prejudices even though these attitudes influence their behavior. Situational effects and social norms also strongly influence the expression of prejudice. Similarly, discrimination is now recognized as largely a complex web of institutional arrangements that produces inequalities between groups. Indeed, the complexity of the phenomenon makes it extremely difficult to study and measure precisely. Discrimination is usually normative. Its structural web outlives its initiators and may not reflect current attitudes. Moreover, discrimination feeds upon itself; it is typically cumulative and self-perpetuating. These changing conceptions have uncovered the reality that the relationship between prejudice and discrimination is not nearly as simple as previously believed. Given the power of long-established and accepted discriminatory norms, many relatively tolerant people routinely discriminate against outgroups without animosity. In turn, anti-discriminatory norms can cause the highly prejudiced to resist acting on their beliefs. To be sure, prejudice is related to discrimination, but not in any simple one-to-one fashion. These considerations have direct implications for social policy designed to combat group discrimination. Structural efforts that increase favorable intergroup contact, such as affirmative action and school desegregation programs, are most likely to diminish both prejudice and discrimination.

Social science conceptions of prejudice, discrimination, and the relationship between the two concepts have changed and become more complex in recent years. Throughout much of the twentieth century, the study of these topics was centered on North America and its racial and ethnic tensions. But increasingly sophisticated twenty-first-century research conducted throughout the world has required broader definitions and theoretical approaches.

Prejudice

Consider first the definition of prejudice. The word 'prejudice' derives from the Latin word *praejudicium* – literally 'before judgment.' And many European languages retain this emphasis on prejudgment today: e.g., *vooroordeel* (Dutch), *Vorurteil* (German), *pregiudizio* (Italian), *preconcello* (Portugese). But modern social science employs the term as signifying not just prejudgment but emotion as well.

Gordon Allport's (1954: p. 9) seminal volume, *the Nature of Prejudice*, offered a straightforward definition that guided research and theory for decades. Ethnic prejudice, he wrote, is "an antipathy based upon a faulty and inflexible generalization. It may be felt or expressed. It may be directed toward a group as a whole, or toward an individual because he is a member of that group." This working definition served social science, and especially social psychology, well because it combined the two key components of the phenomenon – one affective ('antipathy') and the other cognitive ('faulty and inflexible generalization' – better known as a stereotype). Allport wisely chose to omit any link to actual behavior in his definition.

But for some years only one component of Allport's definition received attention. During psychology's 'cognitive revolution' (1960–85), the cognitive features of prejudice were studied intensively by social psychologists while the equally important role of emotion was virtually ignored. Considerable progress was made in understanding stereotypes – gross characterizations of whole human groups. But ignoring affect – hate, envy, threat – rendered an incomplete understanding of prejudice during this period.

Further study, however, uncovered a critical missing element in Allport's approach to prejudice – the situational context in which prejudice is or is not triggered. Consequently, social psychologists now argue for a broader and more precise definition of prejudice. Alice Eagly (Eagly and Diekman, 2005) and her colleagues maintain that a complete definition must consider the social context. Focusing on sexism, Eagly advocates a *role-congruency model*. Women in traditional roles that 'fit' with the female stereotype (e.g., mother, secretary) do not threaten the status quo. Indeed, they typically evoke favorable, although sometimes patriarchal and patronizing, responses. Negative prejudice arises when women occupy 'nonfitting' roles that conflict with the dominant stereotype of females (e.g., business leader, mathematician). These women directly threaten traditional gender norms.

This perception of role incongruence takes place within the larger framework of societal norms. For instance, when enough women rise to head such major American corporations as Lockheed, International Business Machines, and Hewlett-Packard, normative acceptance in the workplace rises even if there remains for sexist individuals a sense of a lack of fit with their stereotypes of women. Discrimination declines for normative and structural reasons although the decline in sexist attitudes may lag in time. Normative change is primarily driving the reduction in discrimination rather than any immediate lessening of prejudice.

Effective measures of sexism reveal this dual view of women (Glick and Fiske, 1996). These scales tap both approval of women in traditional roles and disapproval of them when they seek high-status, nontraditional roles. This phenomenon is called 'ambivalent sexism.' Note that this more subtle and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25086-1

complex form of prejudice acts to resist change in two ways – rewarding those women who do not press for change and punishing those who do. A comparable analysis can be made for racial prejudice.

Consequently, the basic definition of prejudice requires extension. Prejudice will be activated when outgroups threaten the status quo by assuming nontraditional roles that violate established group stereotypes.

A second broadening from Allport's classic definition involves the depth with which prejudice is held. Allport had hinted at this with his assertion that prejudice 'may be felt or expressed.' But research, using an array of different methods, has now shown that prejudice can take a variety of subtle forms – indeed, so subtle that many people are truly unaware of their intolerance and negative outgroup stereotypes. As progress has been made against group discrimination and prejudice in many countries, the older blatant forms of bigotry have receded (but not disappeared) while the more symbolic and subtle forms have increased.

An example of these more subtle forms consists of the withdrawal of positive emotions toward the outgroup without any particular increase in negative feelings (Greenwald and Pettigrew, 2014). Two items have demonstrated this tendency among both European and North American survey samples: "How often have you felt sympathy (or 'admiration') for [outgroup members] who grew up in slums and poverty?" The subtlety of these sympathy and admiration items is indicated by the fact that they are typically *not* seen as reflecting prejudice by most respondents. Yet in seven independent European samples, they not only correlated with other measures of prejudice against immigrants but also predicted prodiscrimination beliefs. Those who reported that they rarely or never felt sympathy or admiration for an immigrant minority in their country were significantly more likely than others to support sending home those immigrants who commit crimes or have no immigration papers.

Another form of these less blatant types of prejudice has been labeled *infrahumanization*. This concept refers to the tacitly held belief that one's ingroup is more human than an outgroup (Leyens et al., 2000). Infrahumanization arises when people reserve 'human essence' for the ingroup and deny it to the outgroup. This process denies the outgroup such secondary emotions as love and attachment. Secondary emotions are what we feel after we first experience such primary emotions as anger, disgust, fear, and happiness. Primary emotions are shared with animals; secondary emotions are thought to be distinctively human. This phenomenon probes the deeper recesses of prejudice that psychoanalytic writers have stressed.

The most studied and surprising of these new methods is the Implicit Association Test (IAT; Banaji and Greenwald, 2013). The basic idea of the test is that associations not accessible to awareness can influence our attitudes and behavior. The IAT, a computer-based measure, requires that users rapidly categorize two target concepts with an attribute (e.g., the concepts 'black' and 'white' with the attribute 'smart'), such that easier pairings (faster responses) are interpreted as more strongly associated in memory than more difficult pairings (slower responses). Thus, if White subjects connect 'white' with 'smart' faster than they manage with 'black' with 'smart,' the IAT records this as a deeply subtle indication of prejudice. The strength of such a measure is that it subverts such widespread problems of explicit self-report methods as the lack of awareness or social desirability bias.

Critics have argued that these new procedures are not assessing prejudice. But consistently these subtle measures have been shown to possess both internal and external reliability and boast correlations with other variables comparable to those of traditional scales of prejudice. The common manner in which those who resist the idea that they are prejudiced is to oppose changes that would benefit stigmatized outgroups – such as affirmative action and desegregated facilities – for ostensibly nonprejudicial reasons.

Another consistent finding of the literally thousands of research studies of prejudice concerns the surprising degree of similarity in findings across different types of prejudice targets and in different nations around the globe. With remarkably few exceptions, prejudice against stigmatized outgroups is typically found to be greater among the elderly, the poorly educated, political conservatives, those with little outgroup contact, and those who score highly on measures of such personality syndromes as authoritarianism and social dominance orientation. The profile of the relatively tolerant is just the opposite: the young, the well educated, political liberals, and those with outgroup contact and low scores on authoritarianism and social dominance orientation (Pettigrew and Tropp, 2011)

Discrimination

A similar broadening of the definition has taken place for understanding intergroup discrimination. The term is derived from the Latin word *discriminatio*, which means to perceive distinctions among phenomena or to be selective in one's judgment. Cognitive psychology retains the first of these meanings, and social science retains the second. But there is also a difference in definitions between the micro- and macrosocial sciences. At the microlevel, discrimination is often viewed as individuals acting to restrict unfairly the resources of others. But at the macro-level, discrimination is employed to describe complex social systems that produce intergroup inequities in social outcomes. It is this second definition, widely used in economics, political science, and especially sociology, that has proven more useful and is the primary focus of this article.

Here again, recent research demonstrates that what initially seemed to be an uncomplicated phenomenon is in reality quite complex. Given the obvious hate involved in the vicious and well-known acts that were perpetrated by White American lynch mobs against African-Americans and Nazis against Jews, it is little wonder that many believe extreme prejudice is normally involved in discrimination. But actually much discrimination occurs without prejudice or even awareness. Discrimination is not, as popularly thought, simply the accumulation of individual acts of unfairness between members of different groups. It consists as well of an elaborate web of institutional arrangements that produces group inequalities across racial, ethnic, gender, or other group lines. Studied throughout the social sciences, these inequalities can involve political power, economic resources, and cultural access.

Standard definitions of discrimination at the macrolevel typically focus on group differences with varying types of qualifications. In sociology, Robin Williams (1947: p. 39; italics added) held that discrimination exists "… to the degree that individuals of a given group who are otherwise *formally qualified* are not treated in conformity …" with how ingroups are treated. In economics, Gary Becker (1968: p. 81; italics added) wrote that economic discrimination occurs "… against members of a group whenever their earnings fall short of the amount *warranted by their abilities.*" But how are we to determine who is 'formally qualified' and what is 'warranted by their abilities'? These significant qualifications to definitions of discrimination raise difficult problems for studying and understanding the phenomenon.

Viewing discrimination from an institutional web perspective casts a wide net, and such definitions leave room for substantial ambiguity. Just what constitutes discrimination and how do you measure it? These questions have both significant policy and legal implications. Disagreement about what constitutes discrimination stems from two sources – one ideological and political and the other empirical. First, because discrimination violates the law and professed values in many countries, a judgment that unequal outcomes reflect discrimination can initiate a demand for unpopular change and costly remedies. Resistance to such change and costs often activates heated debate about the extent of discrimination. Second, deficiencies in analysis and evidence limit the ability of social scientists to trace precisely the dynamic system of effects triggered by discrimination over time.

Consider the political issue. The broadest definitions of discrimination assume that no groups have inherent characteristics that warrant inferior social outcomes. Thus, virtually *all* inequality becomes a legacy of discrimination and a social injustice to be remedied. Favored by the political left, this view appears to most social scientists as too-sweeping. There are obvious reasons for group disparities that most observers would not label as discrimination as revealed by the qualifications made in virtually all the basic definitions of the term.

By contrast, political conservatives favor a narrow definition that limits the concept's scope by including only actions consciously intended to restrict a group's life chances and choices. For several reasons, most social science specialists also reject this formulation. An intentionality criterion returns the concept to the realm of psychology and individual actions while it deflects attention from the critically important restraining social structure. Moreover, the invisibility of intentions creates formidable obstacles for substantiating discrimination. That those responsible for outgroup discrimination deliberately intended to discriminate is exceedingly difficult to prove in a court of law. Finally, the effects of discrimination are the same whether or not the causal institutional mechanisms were intended to produce group inequalities.

This rejection of the intentionality criterion leads to an important distinction between *direct and indirect discrimination*. Direct racial discrimination occurs at points where inequality is generated, often intentionally. When decisions are based explicitly on race, ethnicity, gender, or some other group distinction, discrimination is direct. Indirect discrimination occurs when the inequitable results of direct discrimination serve as a basis for later decisions. Hence, discrimination is indirect when an ostensibly neutral criterion becomes a proxy for the outgroup in determining social outcomes. Indirect discrimination magnifies and perpetuates the original injury into the future. And the older definitions of the phenomenon typically do not allow for the pernicious effects of indirect discrimination.

Wage discrimination illustrates this critical distinction. Direct discrimination exists when employers pay equally qualified members of two groups different rates for the same work. Indirect discrimination exists when the employers pay the two groups unequally because prior discrimination in employment, education, or housing created apparent differences in qualifications or channeled the groups into better- and worse-paying jobs. This direct/indirect distinction resembles the distinction often made by legal systems between disparate treatment and disparate impact. While intentional direct discrimination may have triggered the causal chain, the original injury is perpetuated and magnified by largely unwitting accomplices. To be sure, these accomplices typically benefit from the discriminatory arrangements and have little incentive to alter them. But the important point is that these beneficiaries of the discriminatory practices did not initiate them and may not even be aware of their operation. The discriminatory norms were formed earlier by others, and later generations merely follow the entrenched and long-accepted intergroup norms.

This conceptual complexity carries over to impede the empirical study of discrimination. What may appear as rigorous quantitative analyses often camouflage the crucial issues. An examination of wage *decomposition analysis* illustrates the point. Assessments of racial discrimination produced by decomposing gross group differences in social outcomes are common in both sociology and economics. This approach first assigns one segment of the gross group differential to 'qualifications' and other factors deemed by the researcher as legitimate determinants of social rewards. The residual segment not demonstrably linked to these presumed 'legitimate' determinants of the outcomes is then presented as the estimate of discrimination. But without better information than is usually available and closer agreement on what constitutes discrimination, no unique estimate of discrimination is possible.

This daunting conclusion is the result of the fact that the choice of control variables to index 'legitimate' determinants of social outcomes essentially shapes the answers. Indeed, each such study essentially redefines discrimination with its unique choice of control variables. Any appearance of scientific certitude is an illusion. Not surprisingly, discrimination estimates from this approach using the same basic data vary enormously.

Think about this simple hypothetical example. Two European researchers, using the same data set, each wish to estimate the degree of employment discrimination against first- and second-generation immigrants. The first investigator obtains the employment difference between natives and immigrants and then controls for age, education, gender, and fluency in the national language. The second investigator obtains the same employment differential and controls for the same four variables but adds an additional control for prior work experience (an indicator of indirect discrimination). Obviously, the two investigators have defined discrimination differently. The first researcher, with one less control variable,

will necessarily obtain a larger estimate of discrimination than the second researcher.

Empirical research on group discrimination must mirror the phenomenon in its variety and complexity. The regression decomposition approach is useful but limited. Regression analyses could provide more pertinent information if based on more homogeneous job groups (Conway and Roberts, 1994) and on structural equation models that test reciprocal causation. Most important, if the aim is to guide policy, a framework far more complex than the dichotomous discrimination-or-not approach is required. Research that traces the actual processes of institutional discrimination is essential. Also needed is more attention to victims' perceptions of discrimination and to the changes generated by antidiscrimination efforts.

Two summary propositions emerge from this discussion. First, discrimination is largely normative. Its structural web outlives its initiators and may not reflect current attitudes. Second, discrimination feeds upon itself; it is typically cumulative and self-perpetuating. To be effective, remedies must intervene and reverse its 'vicious circle.'

How Does Prejudice Relate to Discrimination?

Given the complexities involved with both concepts, it is hardly surprising that the relationship between prejudice and discrimination is also complex. One popular view is that there is a simple relationship between the two phenomena: namely, prejudiced individuals of the ingroup discriminate against members of the outgroup while unprejudiced ingroup members do not discriminate. Such a view ignores such important social dynamics as the power of social norms to guide behavior.

On this question, the macro- and micro-social sciences agree (DiTomaso, 2012; Greenwald and Pettigrew, 2014). Sociologists stress the importance of societal structures in producing intergroup discrimination. Such historical realities as past slavery and immigrant poverty are inevitably associated with current differences in employment and wealth and in turn with residential segregation. The resulting lack of intergroup contact provides a breeding ground for perceived difference that can take the form of stereotypes, intergroup threat, and wariness if not outright dislike (Pettigrew and Tropp, 2011). Widespread belief in a 'just-world' can lead to perceiving impoverished outgroups as deserving of their low status, having brought their disadvantages on themselves. In this way, the residue of past discrimination can produce future discrimination as part of a vicious circle (Myrdal, 1944).

Sociologists appeal to *norms* – widely shared understandings of what constitute acceptable social behavior. Both formal norms (e.g., a posted 65-mph automobile speed limit) and informal norms (keeping to the right if driving below the speed limit) powerfully guide behavior (Pettigrew, 1991). Also important are rewards and punishments that support the norms (e.g., an enforced 75-mph speed limit on the same highways). Norms shape intergroup interaction and provide a common meaning to the interaction.

Moreover, discriminatory norms are characteristically cumulative and self-perpetuating. As noted above, normative persistence means that their discriminatory effects typically outlive the initiators of discriminatory practices. The initiators may well have been highly prejudiced; but later generations follow these norms that benefit their ingroup without necessarily harboring the animosity that led to the creation of the norms. As a result, norms are likely to remain unchanged, even while attitudes are shifting markedly. At present, in the midst of rapid formal change in intergroup relations in Northern Ireland, South Africa, and the southern United States, old norms are slowly receding while new equalitarian norms have yet to develop fully. In all three societies, reticence and awkwardness characterize intergroup interaction together with widespread intergroup avoidance and informal discrimination that is not necessarily related to prejudice.

Norms can be strong enough so that people think and behave in conflicting ways in different social contexts without awareness of the inconsistency. At an Indiana Steel Mill in the 1950s, Black and White Americans were members of the same racially desegregated union and worked well together (Reitzes, 1953). Only 12% of the White workers reported low acceptance of African-Americans on the job. Those most involved in the union were the strongest supporters of the union's pro-desegregation norms. But these same White workers also lived in racially segregated, all-White neighborhoods and many belonged to activist pro-segregation neighborhood groups. Indeed, 84% of those who accepted African-Americans at work were highly resistant to Blacks living in their neighborhoods. Those most involved with their neighborhoods were the most resistant. The behavior in each setting favored the setting's prominent ingroup – union solidarity at work, racial solidarity at home.

Social psychologists agree and have extended this sociological analysis. They consider conformity an essential concept for understanding prejudice. Conformity is the link that accounts for how societal forces eventuate into patterns of acceptance or discrimination by individuals. Relatively unprejudiced White Americans generally follow their ingroup's norms. Such norms typically favor their ingroup. If these norms involve preferential treatment of the ingroup, most people – like the Indiana Steel workers – will conform without personal animus toward the outgroup.

Together with conformity, ingroup favorability operates to create discrimination. Quite often ingroup favoritism is hidden even from those who practice it. Consider the way much job recruitment occurs. Good workers are asked frequently to seek out others for job openings. Because of extensive ('de facto') racial segregation in residences, schools, and workplaces, this practice often leads to White workers to draw necessarily on virtually all-White acquaintanceship networks, and thus they recommend only other Whites for the vacancies (Reskin, 1998). By drawing heavily on ingroup ties, this seemingly harmless process can sustain or exacerbate discrimination without the involvement of hostility toward the outgroup.

Thus, relatively unprejudiced people can routinely engage in discrimination, while prejudiced people often do not. Both are following the social norms under which they live. For instance, unprejudiced Whites in the Southern United States of the 1930s had to follow the dominant norms of racial discrimination or face negative consequences in their community. Similarly, highly prejudiced White workers

employed by affirmative action firms in the United States today follow the nondiscriminatory norms of their employer or risk losing their jobs.

In short, different social circumstances can elicit different reactions and override personal attitudes and preferences. But it is important to note that this phenomenon does not deny the potential of prejudice to influence discriminatory behavior. When relevant social norms are not operating, prejudice is likely to relate more closely to discrimination. And even when the norms are operating, the prejudiced and unprejudiced will reveal their differences in the degree of fervor with which they follow the norms. Southern American lynchers and Nazis wreaked their havoc with the support of societal norms; in these instances, individual prejudice and the norms combined with tragic results.

Both experiments and surveys reveal just how strong yet restrained ingroup bias and favoritism can be (Greenwald and Pettigrew, 2014). Blatantly negative stereotypes of the outgroup (e.g., stupid, lazy) are often rejected, but positive stereotypes (e.g., smart, ambitious) are typically assigned more to the ingroup. In effect, the illogic is that 'they' are not worse than 'we,' are but 'we' are better than 'they' are. In addition, equity norms are often compromised. For instance, in competitive game studies, subjects will typically not punish outgroup members, but they will reward ingroup members more if there is some ostensibly 'fair' rationale – such as calling the extra gains a 'bonus.'

The same type of subtle ingroup favorability effects are found in the enormous amount of public opinion survey data gathered over the years on White American attitudes toward racial change. Some of these attitudes have changed dramatically. Surveys of White Americans' racial attitudes over the past 50 years show that Whites have steadily increased their support for policies that provide housing and educational rights for African-Americans. These surveys also reveal White Americans' increasing support for racial intermarriage, equal opportunity in employment, and the acceptability of an African-American candidate for US President. The last of these trends finally came to fruition in 2008.

Yet, White Americans support for policies that provide direct governmental assistance to minorities has been largely unchanged during the past half century. Thus, White Americans have steadily opposed enhanced social services to minorities and affirmative action for under-represented minorities in hiring or college admissions (Schuman et al., 1997).

In other words, national American surveys since 1950 have found that most White Americans accept the basic principles of equal opportunity but still resist the implementation of policies that would bring about equality by directly helping outgroups (Pettigrew, 1979). Nevertheless, ingroup favorability, however, leads a majority of White Americans to favor many government programs that do provide direct assistance largely to themselves – from farm subsidies to tax loopholes and low tax rates on the wealthy.

To sum up, prejudice and discrimination are related, but not in the simple manner as is popularly thought. The prejudiced are more likely to favor and practice discrimination against outgroups. But group discrimination typically arises from long-established norms that most people conform to without hostility or even awareness.

Implications for Social Policy

These major shifts in social science thinking about prejudice and discrimination have significant implications for social policy. The two phenomena are closely related, but not in the simple one-to-one fashion often assumed. Laws and institutional practices that directly counter discriminatory norms are far more likely to reduce intergroup discrimination than attempts limited to reducing prejudice alone. Indeed, the new norms themselves are likely to lessen prejudice as well as discrimination.

Social psychologists have long shown that behavioral changes alter attitudes more easily than do attitudinal changes alter behavior. New norms and new laws can and do change behavior. But, of course, such societal transformations will be resisted when intergroup attitudes are extremely hostile.

Recent advances in the civil rights of gays and lesbians in Europe and North America illustrate this intricate process that weaves prejudice reduction with structural change. In the 1980s, the gay community began to make special efforts to 'come out,' to publicly announce their group status. 'Straights' suddenly discovered that they knew many gays, even friends and family members they did not know previously were gay. Intergroup contact between gays and straights had been widespread, but not until group status was recognized could this contact affect attitudes. Homophobia began to recede, and only then were governments emboldened to legalize same-sex marriage. And this change in the law in turn has led to further reductions in anti-gay prejudice.

Critical to this process is the role of intergroup contact. Social psychologists in many countries have found intergroup contact to be one of the most effective means of reducing prejudice in all of its forms – subtle as well as blatant. If extreme threat is not involved, intergroup contact is surprisingly effective. And a meta-analysis of more than 500 studies conducted in 38 nations shows it is especially effective in diminishing homophobia (Pettigrew and Tropp, 2011).

This process indicates that institutional alterations that further intergroup contact under positive conditions are the most likely to succeed. Desegregated schools and other public facilities as well as affirmative action programs in North America, the Netherlands, and other nations all lead to greater intergroup contact.

Where such programs have taken root, we can expect further decreases in both prejudice and discrimination.

Prejudice in Society: Psychological Perspectives

Jacques-Philippe Leyens, Catholic University of Louvain, Louvain-la-Neuve, Belgium

Abstract

Prejudice went through different waves of research. First, it was considered a trouble of personality. Second, it was seen as the result of normal processes. Third, it implied implicit and explicit ways of reacting, and showed that people are ambivalent. Like aversive racists who believe not to be racists, their prejudice surfaces in ambivalent ways. Many prejudiced reactions are automatic, but control can appear in disguised ways. In the last decade, dehumanization increasingly has been investigated and links with the theory of mind have been established. Possibilities of reducing prejudice are examined at the group and at the individual level.

Prejudice is defined as unfair beliefs, affects, and discriminatory behaviors toward members of a group as a result of their membership to this group. Prejudiced groups may be ethnic or sexual, for instance, and prejudice will take the name of racism and sexism. By definition, prejudice implies generalizations, and many authors defend the idea that the generalizations are irrational or even immoral. Such a view implies that objective truth is attainable. It also overlooks the fact that different ideologies influence the sophisticated ways that prejudice takes.

Prejudice as Individual Differences

Authoritarian personality was the first explanation of prejudice, which derived from an attempt to understand the fascist establishment and ideology (Adorno et al., 1950). This theory based on right-wing socialization was complemented by a more general one focusing on dogmatism (Rokeach, 1960). Recent theorizing gave rise to Altemeyer's (1988) Right-wing authoritarianism and social dominance (Sidanius and Pratto, 1999). Although based on different theoretical premises, intraindividual versus sociostructural questionnaires designed to tap these individual differences often show high correlations.

Prejudice as a Normal Process

In the early 1970s, Tajfel et al. (1971) imagined a minimal group situation that would serve as a baseline to which variables would be added to obtain discrimination between groups. To their surprise, mere categorization sufficed to lead to ethnocentrism, also called ingroup favoritism bias. Although this bias is not necessarily linked to outgroup derogation, researchers interpreted the phenomenon as discriminatory. A misunderstanding of the minimal group situation thus led people to consider that prejudice was a normal and inevitable process that would provide a positive social identity to group members. Tajfel (1981) proposed the social identity theory that became a main worldwide influx to work on intergroup relations and especially on prejudice from the point of view of dominant and dominated groups. With the variables of permeability (vs impermeability), stability (vs instability), and legitimacy (vs illegitimacy), Tajfel offered precise hypothesis concerning individual mobility and social (intergroup) change.

Beliefs in normality were reinforced by uncontrollable behaviors. All people know the negative stereotypes held by different groups and many do not share them. When they are overloaded by a demanding environment and in need of cognitive capacities, however, they may let prejudice leak. Such perspective makes a clear distinction between beliefs or stereotypes, on the one hand, and prejudice, on the other (Devine, 1989). It should be noted, however, that most books on prejudice (or racism) associate it with stereotypes and discrimination.

Prejudice as Ambivalence

Little by little, Myrdal's (1944) *An American Dilemma: The Negro Problem and Modern Democracy* was recognized by the Americans. They recognized that besides their ideas that all humans are equal, they discriminated against blacks. Until now, ambivalent behaviors and theorizing followed.

- Katz et al. (1986) showed that white Americans behaved ambivalently toward blacks. Depending on the salience of ideology, egalitarianism, or meritocracy (also called Protestant work ethics), they thought blacks were equal to them or believed that blacks did not work sufficiently well and did not deserve credit. They behaved accordingly with black targets. It is ambivalent amplification racism.
- Dovidio and Gaertner (1986) described many whites as aversive racists. They sincerely believe to be nonracists but, unconsciously, they cannot but behave as racists. These people are fundamentally ambivalent.
- For instance, when interacting with a black person, aversive racists are able to control their language and come out happy of the exchange. Their partners, however, are not satisfied and treat the whites as hypocritical because their nonverbal behaviors, which are difficult to control, showed signs of uneasiness instead of kindness. Stated otherwise, aversive racists' behaviors are ambivalent.
- Targets of prejudice may be ambivalent (Steele, 1997). Bright black students were asked to answer to a difficult test on verbal fluency. They were instructed that the task was either part of an exercise or a test to gauge their ability. Compared with the performance of white students, the exercise led to similar results, whereas the test induced a poorer performance. In other words, when asked to disconfirm the negative stereotype about blacks,

these bright students confirmed the stereotype. Apparently, the poor performance was due to interfering thoughts while trying to solve the difficult test. The students normally were able to solve the test; however, when asked to disconfirm the reputation of their group, they thought of possible failure. In other words, targets of prejudice were ambivalent.

- Sexism can be an ambivalent theme. So much so that authors (Glick and Fiske, 1996) working on the topic called their theory 'ambivalent sexism.' One might consider that the theory is doubly ambivalent. Many men are hostile toward women as reports of sexual abuse in newspapers daily convince the readers. Ambivalently, the same men may show benevolence toward women. Where the theory is doubly ambivalent is that benevolence is also considered sexist. Rather than measuring routine politeness or gallantry, benevolent sexism includes paternalism, gender differentiation, and intimate heterosexuality. A questionnaire of ambivalent sexism has been tested successfully in an impressive number of countries. Not unsurprisingly, benevolent sexism attracted most attention and the overall results are convincing.
- Stereotypes circulate about any group and may elicit prejudice. Fiske (2011) found a simple stereotype content model that is able to categorize any group. Besides categorization and content, the model also predicts emotions and behaviors toward the groups. The model is based on the two dimensions that are considered essential, and sufficient, for person perception. The two dimensions are competent versus incompetence, and warmth versus cold. The first dimension refers to status and the second one depends on the cooperation – competition relation between groups. Although the two dimensions are not completely orthogonal, they can be treated as such. Four quadrants result. The warm and competent quadrant includes the ingroup and reference groups. It elicits admiration and provokes both active (helping) and passive (associating) protection. The cold and incompetent quadrant includes drug addicts, homeless persons, and Arabs. The emotion is disgust and the behavior is passive (exclusion) and active (attacking) harm. The other two quadrants are ambivalent; they are high on one dimension and low on the other one. The competent but cold quadrant contains rich people, Asians, and Jews. It leads to envy and behaviorally to passive facilitation (uniting) but active harm (fighting). Finally, warm but incompetent groups are pitied and elicit active facilitation (helping) but passive harm (neglecting). Not much is to be said about the warm and competent group. In accordance with social identity theory, it facilitates ingroup favoritism. The other extreme outgroups, incompetent and cold, are special and will receive more attention in the section devoted to dehumanization. Ambivalence describes the last two quadrants and is recognized by the *but* link between the dimensions. They deal with status that divides people. Their main function is to direct comparisons that may be prejudicial as they provoke feelings of envy and scorn. In sum, most outgroups are represented ambivalently.
- Social interactions between members of different groups have been neglected up to recent investigations and theory (Shelton and Richeson, 2006). Research has adopted an individualistic approach. People have beliefs about one another, beliefs about how the other person views them, and beliefs about the interaction. Stress and coping have been the main sources of inspiration. It has been shown that whites and blacks have similar beliefs, although they are afraid to cope for different reasons. They all share the belief that the interaction protagonist is not interested in their encounter, but whites are frightened to be perceived as racists and blacks are scared to be discriminated against. Racial minorities also seek to be respected and to be seen as competent more than do whites, whereas whites seek to be liked and seen as moral more than racial minorities do. These different aspirations lead to misunderstandings, and all of these misinterpretations show the ambivalence that guides these interactions.
- Color-blindness and color-consciousness are two ideologies that provoke a double ambivalence. Color-blind people believe all individuals are equal and, thus, similar. Color-conscious people think that differences between groups must be recognized. Some decades ago, social psychology was unanimously color-blind. Categories were banned. More recent studies have concluded that color-consciousness, favored by minorities, was more efficient when conducting racially mixed encounters. Especially in the United States, people have ambivalent views about these two ideologies. Educated people state that they are in favor of color-consciousness, probably because research says so, but they continue behaving in color-blind ways. Groups (whites, blacks, women, for instance) should not be singled out in a conversation; minorities' strengths (music, sport, sensitivity) become politically incorrect because they are widely spread within a dominated group. Even mere thinking about a stereotype is considered a sin. Color-conscious people are convinced that they perceive equality among targets. Thus, they have ambivalence in the perception of these two different ideologies. The second ambivalence lies within each perspective. Color-blindness contains two strategies. On the one hand, the world should be inhabited only by individuals who are equal. On the other hand, color-blindness implies that minorities assimilate to the majority and, consequently, is a prejudiced strategy. Color-consciousness also includes two strategies. Either group boundaries are accepted and respected, or they are recognized without respect. These two strategies represent integration or explicit racism, but they both send clear signals to their targets allowing a good performance when having to collaborate. Majorities prefer assimilation, whereas minorities favor integration. Curiously, showing signs of group membership upsets people who defend an individualistic world (Maquil et al., 2009). The general field of research on interactions between majorities and minorities is also ambivalent because it is conducted without reference to the domain of the contact hypothesis, and inversely, contact research is conducted without any links with interaction studies.

Automaticity and Social Control

During the decade preceding this century, automatic (unconscious, implicit, nonconscious) process was pitted against

controlled (conscious, explicit, self-reported) process. Theories and methods considered both processes to be mutually exclusive. Theories followed the cognitive view that the two processes were to be given specific attention. Methods measured separately automatic versus controlled responses. Priming, masking priming, and speed were used to obtain automatic responses nearly impossible to avoid. Control was considered time consuming and effortful in contrast to automaticity.

The new century suggested that no response is process pure (Devine and Sharp, 2009). Theories and methods addressed simultaneous attention to the mix of automaticity and control. New research showed limits in the inevitability of stereotypes activation as well as evidence in favor of the malleability of automatic intergroup biases. It also revealed that control does not necessarily need much intentional effort.

Several variables moderate automatic responding. It is the case of restricted attention. When responses are not processed in a meaningful way because of attentional restrictions, automaticity does not seem to play a role. The environment is another variable; viewing people in front of a church or within a prison leads to different responses. Social roles and appearance of targets are a third variable; for instance, Negroid versus less Negroid face features color the responses. Motivation is a fourth variable. Neural activity reveals that physicians do not respond to pain like laypeople. Physicians inhibit empathy, but it remains a neurosciences question whether this inhibition is conscious or unconscious (Decety, 2011).

Automaticity is malleable, because of practice and counterstereotypic examples (e.g., Nelson Mandela). These variables interfere with the deeply rooted socialization that made some stereotypes almost inevitable. The result of this is that malleability is limited. For instance, it is hard to erase the idea that anger is typical of blacks.

Gaunt et al. (2002) showed the interplay of automatic and controlled processes. Using Jacoby's (1991) process dissociation, they proportioned the role of automatic and familiar responses from the one of control when having to memorize liked and disliked racial stereotypes. The same procedure has been utilized by other researchers to verify, for instance, whether race affected the shooting of black and white criminal suspects.

Neurosciences have attempted to provide more powerful evidence to the interplay between automatic and controlled responses. Readers should realize that this evidence is particularly descriptive and that, up to now, it does not contribute much to theoretical advances. The role of median prefrontal cortex (mPFC) in social cognition will be alluded to later. A study by Cunningham et al. (2004) is famous for showing neural activity of automaticity and control. The latter processes were activated by showing black and white faces at subminimal and supraliminal speeds. Participants' task was to locate the faces. When rapid, automatic responses were activated, there was greater activity of the amygdala for blacks than for whites. The amygdala is known to be a sign of fear. When there was control, the dorsal anterior cingulated cortex and lateral prefrontal cortex (LPFC) were particularly active when viewing black faces. This means mere attention. Moreover, the ventral region of LPFC was also activated more for black faces, which suggests inhibition of a given response. The different regions when the speed was low may show a double response: attention and inhibition.

Dehumanization

To find what is human, one may look at what is uniquely human (e.g., secondary emotions such as love, admiration, contempt, or shame) or what is typically human (e.g., personality traits common to humans, such as curious, friendly, impatient, or jealous). Ingroup members attribute more positive and negative secondary emotions to their group than to (many) outgroups. Primary emotions, shared with animals, should not differ between ingroup and outgroup (Leyens et al., 2001, 2007). Because ingroup members are perceived as human, stimuli linked to them are also humanized. This phenomenon has been called infrahumanization (Leyens et al., 2000) or animalistic dehumanization; it is mainly an intergroup process. It complements a mechanistic dehumanization (Haslam, 2006) on the basis of typically human characteristics. Such a name implies that people lacking typical attributes become like robots. It is an individual and intergroup process. Individuals and ingroups give more negative typical features to them or to their group than they give to ingroup members and to outgroups. A third approach to humanity derives from the theory of mind. The mind has two dimensions: agency and experience (Gray et al., 2007). Infrahumanization is linked especially to agency, but it also relates to experience. Mechanistic dehumanization works mainly with experience and shows some degree of agency too.

Research on infrahumanization has shown that the ingroup may be particularly humanized, that outgroups are dehumanized, or that both processes work simultaneously. Conflict and dislike are unnecessary to obtain infrahumanization, but ingroup members must be identified with their group. Status and power of the ingroup moderate the effects. High-status groups or powerful groups infrahumanize more than do low-status or dominated groups.

The more adjectives that were estimated to be descriptive of people in the cold and incompetent quadrant of the stereotype model, the more inhuman they were rated. Such a result relates more to dehumanization than with infrahumanization (Vaes and Paladino, 2010). Moreover, exemplars of groups of drug addicts and homeless people were shown to people in a scanner who had to say which emotion they felt. Exemplars of groups belonging to the other quadrants were also displayed with the instruction to reveal the emotion. Functional magnetic resonance imaging was taken. The mPFC was proven to react to social cognition. Whereas mPFC was activated for regular people, it did not respond to members of cold and incompetent groups. In fact, these members showed neural activation linked to disgust (Harris and Fiske, 2006).

Reduction of Prejudice

Contact Hypothesis

Many authors claim that the best predictor of prejudice reduction is intergroup contact. According to all researchers, this contact must meet conditions spelled out by Allport (1954): equal group status within the situation, common goals, intergroup cooperation, and the support of institutional authorities. It was also considered that the contact situation must provide opportunity to become friends. US scholars

favor decategorization to meet these conditions. Europeans, accustomed to many countries, defend the idea that boundaries have to be respected. Stated otherwise, US researchers plead for diminished group saliency, whereas European authors privilege increased group saliency. This opposition evokes the notion of color-blindness versus color-consciousness. Pettigrew (1998) saw a solution in taking time into account. First, essential contact conditions and individual differences should lead in a first phase to decategorization. When trust is settled between groups, there could be salient categorization, also called harmonious differentiation. In a third phase, groups could envisage uniting and forming a new group, called recategorization.

This causal sequence with contact leading to reduced prejudice is still problematic. Prejudice also elicits unpleasant contact. This possibility explains the importance of friendship while the contact is established and allows for the performance of common tasks. The US Armed Forces are known to constitute an example of success concerning racial contacts. With little doubt, this success is due to the conjunction of the essential facilitating conditions. By contrast, difficulties in school desegregation showed the lack of ability to meet these same conditions.

The contact hypothesis does not work similarly in high-status and low-status groups (Tropp and Pettigrew, 2005). Meta-analysis reveals that the relationships between contact and prejudice tend to be weaker among members of minority status groups than among members of majority status groups. This difference may be due the perception of contact by minorities. Dominated groups enter less easily into contact because they view it negatively. It is not really a question of anxiety as minorities perceived a significant social distance in intergroup contact (Binder et al., 2009).

Individualistic Models

In addition to the categorical models evoked in the contact hypothesis (decategorization, harmonious differentiation, and recategorization), an approach relies mostly on the intellectual (and somewhat emotional) abilities of individuals to consider evidence contradictory to their prejudice. Three models have been proposed as possible ways to reduce prejudice.

The Conversion Model

According to the conversion model, which could also be called the Desmond Tutu or Nelson Mandela model, an encounter with an atypical member of a disliked group could provoke a conversion that would generalize to the whole category. Empirical evidence is scarce.

The Bookkeeping Model

In the bookkeeping model, people integrate different pieces of information that they receive from members of stigmatized groups and that contradict their beliefs. Reduction of prejudice would be proportionate to the contradicting information. Empirical evidence exists but is not overwhelming.

The Subtyping Model

When confronted with contradicting information, people try to subcategorize the exceptions to maintain their representations of the whole category intact. A strategy often is used in which representations are made such as, "These women are unemotional; but they are not real women, they are businesswomen."

Reconciliation

Intergroup conflicts have attracted much attention since the Cold War between the United States and the former Soviet Union. The realist approach takes into account rational actors who bargain. Several scholars have recommended initiating cooperative gestures. The opponent feels the need to respond in the same perspective, and bargains may lead to agreements (Nadler et al., 2008). Recent research looks at reconciliation in the path of the Trust and Reconciliation Commission in South Africa. Intergroup reconciliation now investigates how to reduce emotional barriers blocking potential solutions. A minimum of trust is supposed to exist between the victims and perpetrators. Trust, however, does not suffice. Dominated groups suffer because they are represented as powerless; they thus come to discussions with a focus on conflicting matters and the wish to regain some power. Dominating groups, on the other hand, experience the feeling of lacking morality. They will take part in meetings with dominated members with the hope that they will be recognized as moral actors. To this aim, they propose compromising matters. As a result, conflicting points are opposed to conciliation efforts. This distinction is parallel to the search for power and for morality. Time is necessary to expose respective ethnocentrism. Studies suggest that these different ethnocentrisms need to be respected rather than risk having these groups remove their trust.

Prejudice in Society: Sociological Perspectives

Richard T Schaefer, DePaul University, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Prejudice is a negative attitude that rejects an entire group; discrimination is behavior that deprives a group of certain rights or opportunities. Prejudice does not necessarily coincide with discrimination, as is made apparent by a typology developed by sociologist Robert Merton. Several theories have been advanced to explain prejudice: scapegoating, exploitation, and the normative approach. Although widespread expression of prejudice has declined, color-blind racism allows the status quo of racial and ethnic inequality to persist. Prejudice is not limited to the dominant group; members of subordinate groups often dislike one another. The mass media seem to be of limited value in reducing prejudice and may even intensify ill feeling. Equal-status contact and the shared-coping approach may reduce hostility between groups, but data show few friendships cross racial lines. In response to increasing diversity in the workplace, corporations and organizations have mounted diversity training programs to increase organizational effectiveness and combat prejudice.

Prejudice is a negative attitude toward an entire category of people. The two important components in this definition are attitude and entire category. Prejudice involves attitudes, thoughts, and beliefs, not actions.

A prejudiced belief leads to categorical rejection. Prejudice is not disliking someone you meet because you find his or her behavior objectionable. It is disliking an entire racial or ethnic group, even if you have had little or no contact with that group. A college student who requests a room change after 3 weeks of enduring his or her roommate's sleeping all day, playing loud music all night, and piling garbage on his or her desk is not prejudiced. He or she is displaying prejudice, however, if he or she requests a change on arriving at school and learning from his or her roommate's luggage tags that his or her new roommate is of a different nationality.

Distinguished from Discrimination

Prejudice is related and sometimes confused with discrimination. The sociological perspective of prejudice distinguishes it from discrimination. Prejudice and discrimination are related concepts but are not the same. Prejudice is a belief or attitude; discrimination is action. Discrimination involves behavior that excludes all members of a group from certain rights, opportunities, or privileges. Like prejudice, it must be categorical. If an individual refuses to hire as a typist an Italian American who is illiterate, it is not discrimination. If an individual refuses to hire any Italian Americans because he or she thinks they are incompetent and does not make the effort to see if an applicant is qualified, it is discrimination.

Merton's Typology

Prejudice does not necessarily coincide with discriminatory behavior. Sociologist Robert Merton (1949, 1976), in exploring the relationship between negative attitudes and negative behavior, identified four major categories. The label added to each of Merton's categories may more readily identify the type of individual being described. These are as follows:

Type I: The unprejudiced nondiscriminator: all-weather liberal
Type II: The unprejudiced discriminator: reluctant liberal
Type III: The prejudiced nondiscriminator: timid bigot
Type IV: The prejudiced discriminator: all-weather bigot

Liberals, as the term is employed in Types I and II, are committed to equality among people. The all-weather liberal believes in equality and practices it. Merton was quick to observe that all-weather liberals may be far removed from any real competition with subordinate groups such as African-Americans or women. Furthermore, such people may be content with their own behavior and may do little to change themselves. The reluctant liberal is not even this committed to equality among groups. Social pressure may cause such a person to discriminate. Fear of losing employees may lead a manager to avoid promoting women to supervisory capacities. Equal-opportunity legislation may be the best way to influence the reluctant liberals.

Types III and IV do not believe in equal treatment for racial and ethnic groups, but they vary in their willingness to act. The timid bigot, Type III, will not discriminate if discrimination costs money or reduces profits or if he or she is pressured not to by peers or the government. The all-weather bigot unhesitatingly acts on the prejudiced beliefs that he or she holds.

LaPiere Study

Merton's typology points out that attitudes should not be confused with behavior. People do not always act as they believe. Close to a century ago, Richard LaPiere (1934, 1969) exposed the relationship between racial attitudes and social conduct. From 1930 to 1932, LaPiere traveled throughout the United States with a Chinese couple. Despite an alleged climate of intolerance of Asians, LaPiere observed that the couple was treated courteously at hotels, motels, and restaurants. He was puzzled by the good reception they received; all the conventional attitude surveys showed extreme prejudice by Whites toward the Chinese.

Was it possible that LaPiere had been fortunate during his travels and consistently stopped at places operated by the

tolerant members of the dominant group? To test this possibility, he sent questionnaires asking the very establishments at which they had been served if the owner would "accept members of the Chinese race as guests in your establishment." More than 90% responded no, even though LaPiere's Chinese couple had been treated politely at all the establishments. How can this inconsistency be explained? People who returned questionnaires reflecting prejudice were unwilling to act based on those asserted beliefs: they were timid bigots.

The LaPiere study is not without flaws. First, he had no way of knowing whether the respondent to the questionnaire was the same person who had served him and the Chinese couple. Second, he accompanied the couple, but the questionnaire suggested that the arrival would be unescorted (and in the minds of some, uncontrolled) and perhaps would consist of many Chinese individuals. Third, personnel may have changed between the time of the visit and the mailing of the questionnaire (Deutscher et al., 1993).

Attitudes are not important in small matters, they are important in other ways: Lawmakers legislate and courts may reach decisions based on what the public thinks. This is not just a hypothetical possibility. Legislators in the United States are often persuaded to vote in a certain way by what they perceive as changed attitudes toward immigration, affirmative action, school busing, abortion, national health care, and prayer in public schools.

We examine the theories of why prejudice exists from the sociological perspective, which would fall in to Merton's Types III and IV above and discuss the content and extent of prejudice today.

Theories of Prejudice

Prejudice is learned. Friends, relatives, newspapers, books, movies, and television all teach it. Awareness begins at an early age that there are differences among people that society judges to be important. Several theories have been advanced to explain the rejection by individuals of certain groups in a society.

Exploitation Theory

Racial prejudice is frequently used to justify keeping a group in a subordinate position such as a lower social class. Conflict theorists, in particular, stress the role of racial and ethnic hostility as a way for the dominant group to keep intact its position of status and power. Indeed, this approach maintains that even the less-affluent White working class uses prejudice to minimize competition from upwardly mobile minorities.

This exploitation theory is clearly part of the Marxist tradition in sociological thought. Karl Marx emphasized the exploitation of the lower class as an integral part of capitalism. Similarly, the exploitation or conflict approach explains how racism can stigmatize a group as inferior so that the exploitation of that group can be justified. As developed by Oliver Cox (1942), exploitation theory saw prejudice against Blacks as an extension of the inequality faced by the entire lower class.

Exploitation theory does not necessarily explain prejudice in all its forms. First, not all minority groups are exploited economically to the same extent. Second, many groups that have been the victims of prejudice have not been persecuted for economic reasons – for example, the Quakers. Nevertheless, as Gordon Allport (1979) concludes, the exploitation theory correctly points a finger at one of the factors in prejudice, that is, the rationalized self-interest of the upper classes.

Scapegoating Theory

Scapegoating theory says that prejudiced people believe that they are society's victims. Exploitation theory maintains that intolerant individuals abuse others, whereas scapegoaters feel that they are being abused themselves. The term scapegoat comes from a biblical injunction telling the Hebrews to send a goat into the wilderness to symbolically carry away the people's sins. Similarly, the theory of scapegoating suggests that an individual, rather than accepting guilt for some failure, transfers the responsibility for failure to some vulnerable group. In the major tragic twentieth-century example, Adolf Hitler used the Jews as the scapegoat for all German social and economic ills in the 1930s. This premise led to the passage of laws restricting Jewish life in pre–World War II Germany and eventually escalated into the mass extermination of Europe's Jews. Scapegoating of Jews persists. A national survey in 2009 showed that one out of four people in the United States blame 'the Jews' for the recent financial crisis. *Anti-Semitism* – anti-Jewish prejudice and discrimination – remains a very real phenomenon (Malhotra and Margalit, 2009).

Like exploitation theory, scapegoating theory adds to our understanding of why prejudice exists but does not explain all its facets. For example, scapegoating theory offers little explanation of why a specific group is selected or why frustration is taken out on the real culprit when it is possible. Also, both the exploitation and the scapegoating theories suggest that every individual sharing the same general experiences in society would be equally prejudiced, but that is not the case. Prejudice varies among individuals who would seem to benefit equally from the exploitation of a subordinate group or who have experienced equal frustration.

Normative Approach

Although personality factors are important contributors to prejudice, normative or situational factors must also be given serious consideration. The normative approach takes the view that prejudice is influenced by societal norms and situations that serve to encourage or discourage the tolerance of minorities.

Analysis reveals how societal influences shape a climate for tolerance or intolerance. Societies develop social norms that dictate not only what foods are desirable (or forbidden) but also what racial and ethnic groups are to be favored (or despised). Social forces operate in a society to encourage or discourage tolerance. The force may be widespread – for example, the pressure on White Southerners to oppose racial equality while there was slavery or segregation. The influence of social norms may be limited – for example, one male who finds himself becoming more sexist as he competes with three females for a position in a prestigious law firm.

Social psychologist Thomas Pettigrew (1958, 1959) collected data that substantiated the importance of such social norms in developing a social climate conducive to the expression of prejudice. Pettigrew found that Whites in the South were more anti-Black than Whites in the North, and that Whites in the United States were not as prejudiced as Whites in the Republic of South Africa.

The Content of Prejudice: Stereotypes

An important approach by sociologists and other social scientists to the understanding of prejudice has been the role that stereotypes play. Numerous scientific studies have been made of these exaggerated images.

The systematic study of stereotypes began with David Katz and Kenneth Braly's (1933) use of the *checklist approach*. College students were presented with a list of 84 adjectives such as *sly*, *cruel*, *neat*, and so on. They were asked to list which traits they considered most characteristic of 10 groups: Germans, Italians, Irish, English, Blacks, Jews, Americans, Chinese, Japanese, and Turks. The students' selection of traits for each group consistently agreed with one another, especially for Blacks and Jews. Several other researchers have confirmed this technique.

Scholarship on stereotyping has acknowledged that the stigmatizing of subordinate groups (or out-groups) can take different forms. Social psychologist Susan Fiske and her associates have developed a stereotype content model (SCM) that considers stereotypes along two dimensions. The 'warmth' dimension examines whether the prejudice regards members of other groups as not competitive for scarce resources and therefore warmly or are competitive and therefore with less warmth. The other dimension is 'competence,' which considers whether the object or prejudice is of high social status or not.

Like Merton's approach, this leads to four types. Examples of groups within the combinations of high and low levels of warmth and competence are as follows:

Type I: Competitive, low-status groups: the paternalistic stereotype (for example: the elderly and people with disabilities)

Type II: Noncompetitive, low-status groups: the contemptuous stereotype (for example: the poor and welfare recipients)

Type III: Noncompetitive, high-status groups: the admiration stereotype (for example: other members of one's own group and close allies)

Type IV: Competitive, high-status groups: the envious stereotype (for example: Asians and Jews and people who are wealthy)

This model has allowed a more detailed analysis of the content of prejudice as well as the different forms of expressions such as contempt toward Type II and resentment toward Type IV. Also, stereotypes may be ambivalent as with Type I where one may feel members of the out-group (for example, the elderly) are nice but incompetent (Fiske et al., 2002; Cuddy et al., 2008).

The SCM has held up in understanding prejudice in societies outside the United States. In one study conducted in seven European and three East Asian nations, SCM continued to prove its utility. The one exception was that in the more collectivist cultures of Hong Kong, Japan, and South Korea, there was less willingness to endorse the admiration stereotype (Type III) toward people like themselves even though the respondents did negatively stereotype out-groups (Cuddy et al., 2009).

Labels take on such strong significance that people often ignore facts contradicting their preformed beliefs. People who believe many Italian Americans to be members of the Mafia disregard law-abiding Italian Americans. Muslims are regularly portrayed in a violent, offensive manner that contributes to their being misunderstood and distrusted. Gradually, the mass media – movies, television, newspapers, and periodicals – are presenting a more accurate, evenhanded portrayal of racial, ethnic, and religious groups; however, there is significant room for improvement.

Although explicit expressions of racial and ethnic stereotypes in the media are becoming less common, it is much too soon to write the obituary of racial and ethnic stereotypes. In addition, stereotyping is not limited to racial and ethnic groups. Other groups are subjected to stereotyping. Probably easiest to see in daily life and the mass media is sexism. Sexism is the ideology that one sex is superior to the other. Images and descriptions of women and even girls often reinforce sexism. *Homophobia*, the fear of and prejudice toward homosexuality, is present in every facet of life: the family, organized religion, the workplace, official policies, and the mass media. Like the myths and stereotypes of race and gender, those about homosexuality keep gay men and lesbian women oppressed as a group and may also prevent sympathetic members of the dominant group, the heterosexual community, from supporting them.

In the wake of the 9/11 attacks on the World Trade Center, there has been renewed interest in racial profiling and the degree to which it relies on stereotypes. Profiling by law enforcement officers, including customs officials, airport security, and police, assumes that people fitting certain descriptions are likely to be engaged in something illegal.

Racial profiling persists despite overwhelming evidence that it is not a predictive approach toward identifying potential troublemakers. Whites are more likely to be found with drugs in the areas in which minority group members are disproportionately targeted. A federal study made public in 2005 found little difference nationwide in the likelihood of being stopped by law enforcement officers, but African-Americans were twice as likely to have their vehicles searched, and Latinos were five times more likely. A study of New York City police officers describing some 4.43 million stops between 2004 and mid-2012 found that Blacks and Latinos accounted for 83% of people who were stopped and frisked, and a related study found that Whites were 50% more likely to be carrying weapons (Center for Constitutional Rights, 2011; Goldstein, 2013; Herbert, 2010; Tomaskovic-Devey and Warren, 2009).

Are stereotypes held only by dominant groups about subordinate groups? The answer is clearly no. White Americans even believe generalizations about themselves, although admittedly these are rather positive. Subordinate groups also hold exaggerated images of themselves. Studies

before World War II showed a tendency for Blacks to assign to themselves many of the same negative traits assigned by Whites. Today, African-Americans, Jews, Asians, and other minority groups largely reject stereotypes of themselves, although subordinate groups will to some degree stereotype each other.

The Extent of Prejudice

Interest in developing theories of prejudice or studying its concept has been exceeded only by interest in measuring it. From the outset, efforts to measure prejudice have suffered from disagreement over exactly what constitutes intolerance and whether there is such a phenomenon as no prejudice at all. Add to these uncertainties the methodological problems of attitude measurement, and the empirical study of prejudice becomes an undertaking fraught with difficulty.

The extent of prejudice can be measured only in relative, rather than absolute, differences. We cannot accurately say, for example, that prejudice toward Puerto Ricans is four times greater than that toward Portuguese Americans. We can conclude that prejudice is greater toward one group than toward the other; we just cannot quantify how much greater. The social distance scale is especially appropriate to assess differences in prejudice.

The Social Distance Scale

Robert Park and Ernest Burgess (1921: 440) first defined *social distance* as the tendency to approach or withdraw from a racial group. Emory Bogardus (1968) conceptualized a scale that could empirically measure social distance. His social distance scale is so widely used that it is frequently referred to as the Bogardus scale.

The scale asks people how willing they would be to interact with various racial and ethnic groups in specified social situations. The situations describe different degrees of social contact or social distance. The seven items used, with their corresponding distance scores, follow. People are asked if they would be willing to admit each group:

To close kinship by marriage (1.00)
To my club as personal chums (2.00)
To my street as neighbors (3.00)
To employment in my occupation (4.00)
To citizenship in my country (5.00)
As only visitors to my country (6.00)
Would exclude from my country (7.00)

A score of 1.00 for any group would indicate no social distance and therefore no prejudice. The social distance scale has been administered to many different groups in other countries as well. Despite some minor flaws and certain refinements needed in the scale, the results of these studies are useful and can be compared.

The data from social distance studies over several generations have shown a decided decline in the expression of prejudice even if distinctions remain – that is, people still place groups at different degrees of social distance from themselves. This is a part of a larger trend in sociological research that shows a marked decline in expression of prejudice III in social surveys. However, scholars have cautioned that more tolerance toward direct questions seeking to tap racism may exaggerate the degree of true change in social attitudes (Parrillo and Donoghue, 2013).

Color-Blind Racism

The sociological approaches of exploitation, scapegoating, and normative were developed by measuring people's fairly explicit expressions of prejudice such as, 'I would not vote for a woman for President' or 'I would not want to have Roma or Gypsies living in my community.' Over the last three generations, surveys have consistently shown declining amounts of explicit prejudice being expressed. Yet, casual observations still show deep-seated distrust and intolerance, which often explode in to violence or what have been termed hate crimes.

Color-blind racism refers to the use of race-neutral principles to defend the racially unequal status quo. Yes, 'no discrimination for college admission' should exist, yet the disparity in educational experiences means that formal admissions criteria will privilege White high school graduates. 'Health care is for all,' but if you do not have workplace insurance, you likely cannot afford it.

Color-blind racism has also been referred to as laissez-faire, postracialism, or aversive racism, but the common theme is that notions of racial inferiority are rarely expressed and that proceeding color-blind into the future will perpetuate inequality. In the post-civil rights era and with the election of President Barack Obama, people are more likely to assume discrimination is long past and express views that are more proper – that is, lacking the overt expressions of racism of the past.

An important aspect of color-blind racism is the recognition that race is rarely invoked in public debates on social issues. Instead, people emphasize lower social class, the lack of citizenship, or illegal aliens; these descriptions serve as proxies for race. Furthermore, the emphasis is on individuals failing rather than recognizing patterns of groups being disadvantaged. This leads many White people to declare that they are not racist and that they do not know anyone who is racist. It also leads to the mistaken conclusion that more progress has been made toward racial and ethnic equality and even tolerance than has really taken place.

Economically less-successful groups such as African-Americans and Latinos have been associated with negative traits to the point that issues such as urban decay, homelessness, welfare, and crime are viewed as race issues, even though race is rarely mentioned explicitly. Besides making it harder to resolve difficult social issues, this is another instance of blaming the victim. These perceptions come at a time the willingness of the government to address domestic ills is limited by increasing opposition to new taxes and continuing commitments to fight terrorism here and abroad. The color line remains, even if more people are unwilling to accept its divisive impact on everyone's lives (Ansell, 2008; Bonilla-Silva, 2006; Bonilla-Silva and Seamster, 2011; Kang and Lane, 2010; Winant, 2004: 106–108).

Mood of the Subordinate Group

Sociologists have noted that approaches to prejudice often focus solely on intolerance of the powerful toward out-groups. However, this is an incomplete picture, as one should also consider prejudice directed among out-groups toward each other and even prejudice that people direct inward (Shelton, 2000).

Sociologist William E.B. Du Bois relates an experience from his youth in a largely White community in Massachusetts. He tells how, on one occasion, the boys and girls were exchanging cards, and everyone was having a lot of fun. One White girl, a newcomer, refused his card as soon as she saw that Du Bois was Black. He wrote that he was "shut out from their world by a vast veil" (Du Bois, 1903: 2). In using the image of a 'veil,' Du Bois describes how members of subordinate groups learn they are being treated differently. In his case and that of many others, this leads to feelings of contempt toward all Whites that continue for a lifetime.

Prejudice is as diverse as the nation's population. It exists not only between dominant and subordinate peoples but also among specific subordinate groups. Unfortunately, until recently, there was little research on this subject except for a few social distance scales administered to racial and ethnic minorities. A recent study documents that prejudice among Korean and Dominican immigrants and Black Americans (Roth and Kim, 2013).

Reducing Prejudice

The obvious way to eliminate prejudice is to eliminate its causes: the desire to exploit, the fear of being threatened, and the need to blame others for one's own failure. But how can one on a societal level strive to reduce prejudice?

Much research has been done to determine how to change negative attitudes toward groups of people. The most encouraging findings point to education, mass media, intergroup contact, and workplace training programs.

Education

Most research studies show that well-constructed educational programs have a positive effect on reducing prejudice, at least temporarily. The reduction is rarely as much as one might want, however. The difficulty is that a single program is insufficient to change lifelong habits, especially if little is done to reinforce the program's message once it ends. Persuasion to respect other groups does not operate in a clear field, because, in their ordinary environments, people are still subjected to situations that promote prejudicial feelings (Allport, 1979).

Studies document that increased formal education, regardless of content, is associated with racial tolerance. Research data show that highly educated people are more likely to indicate respect and liking for groups different from themselves. Why should more education have this effect? It might promote a broader outlook and make a person less likely to endorse myths that sustain racial prejudice. Formal education teaches the importance of qualifying statements such as "even though they have lower test scores, you need to remember the neighborhoods from which they come." Education introduces one to the almost indefinite diversity of social groups and the need to question rigid categorizations, if not reject them altogether. Colleges increasingly include a graduation requirement that students complete a course that explores diversity or multiculturalism. Another explanation is that education does not reduce intolerance but instead makes people more careful about revealing it. Formal education may simply instruct people in the appropriate responses. Despite the lack of a clear-cut explanation, either theory suggests that the continued trend toward a better-educated population will contribute to a reduction in overt prejudice (Schaefer, 1986, 1996).

Mass Media

Mass media, like schools, may reduce prejudice without requiring specially designed programs. Television, radio, motion pictures, newspapers, magazines, and the Internet present only a portion of real life, but what effect do they have on prejudice if the content is racist or antiracist, sexist or antisexist? As with measuring the influence of programs designed to reduce prejudice, coming to strong conclusions on mass media's effect is hazardous, but the evidence points to a measurable effect.

The absence of racial and ethnic minorities in television and motion pictures is well documented. They are less likely to play recurring roles and are far underrepresented in key decision-making positions such as directors, producers, and casting agents. Television series are only part of the picture. Whites do news broadcasting predominantly, and local news emphasizes crime, often featuring Black or Hispanic perpetrators; print journalism is nearly the same (Media Matters for America, 2013; Writers Guild of America West, 2013).

Equal-Status Contact

An impressive number of research studies have confirmed the *contact hypothesis*, which states that intergroup contact between people of equal status in harmonious circumstances causes them to become less prejudiced and to abandon previously held stereotypes.

The key factor in reducing hostility, in addition to equal-status contact, is the presence of a common goal. If people are in competition, as already noted, contact may heighten tension. However, bringing people together to share a common task has been shown to reduce ill feelings when these people belong to different racial, ethnic, or religious groups (Fine, 2008; Paluck and Green, 2009).

The limited amount of intergroup contact because of segregated neighborhoods, schools, and workplaces, is of concern given the power of the contact hypothesis. If there is no positive contact, then how can we expect a decrease in prejudice? National surveys show prejudice directed toward Muslim Americans, but social contact bridges that hatred. In a 2006 survey, 50% of people who were not acquainted with a Muslim favored special identification for Muslim Americans, but only 24% of those who knew a Muslim embraced that same view.

Similarly, people personally familiar with Muslims are more than one-third less likely to endorse special security checks just for Muslims and are less nervous to see Muslim men on the same flight with themselves. Although negative views are common toward Muslim Americans today, they are much less likely to be endorsed by people who have had intergroup contact (Saad, 2006).

As African-Americans and other subordinate groups slowly gain access to better-paying and more-responsible jobs, the contact hypothesis takes on greater significance. Usually, the availability of equal-status interaction is taken for granted; yet, in everyday life, intergroup contact does not conform to the equal-status idea of the contact hypothesis. Furthermore, as we have seen, in a highly segregated society such as the United States, contact tends to be brief and superficial, especially between Whites and minorities. The apartheid-like friendship patterns prevent us from learning firsthand not just how to get along but also how to revel in interracial experiences (Bonilla-Silva and Embrick, 2007; Miller, 2002).

Corporate Response: Diversity Training

Prejudice carries a cost. This cost is not only to the victim but also to any organization that allows prejudice to interfere with its functioning. Workplace hostility can lead to lost productivity and even staff attrition. Furthermore, if left unchecked, an organization – whether a corporation, government agency, or nonprofit enterprise – can develop a reputation for having a 'chilly climate.' If a business has a reputation that it is unfriendly to people of color or to women, qualified people are discouraged from applying for jobs there and potential clients might seeking products or services elsewhere.

It is difficult to make broad generalization about the effectiveness of diversity training programs because they vary so much in structure between organizations. At one extreme are short presentations that seem to have little support from management. People file into the room feeling it is something they need to get through quickly. Such training is unlikely to be effective and may be counterproductive by heightening social tensions. At the other end of the continuum is a diversity training program that is integrated into initial job training, reinforced periodically, and presented as part of the overall mission of the organization, with full support from all levels of management. In such businesses, diversity is a core value, and management demands a high degree of commitment from all employees.

Remarkably, the prevalence of any diversity programs in organizations remains slow (10–30%), even after more than 30 years since the diversity-management paradigm was first widely viewed as good for business. Even inexpensive steps are not widely adopted. Unfortunately, corporations with lower representation of women and minorities are less likely to embrace diversity programs.

Research into different corporate policies has found two that are particularly effective. Diversity task forces that bring together people from different departments to brainstorm about opening up hiring opportunities appear to eventually increase the diversity in upper management. A second successful policy is the diversity mentoring programs designed for aspiring women and minorities, as well as White men, to achieve their career goals. Unfortunately, research suggests that if White men perceive African-Americans are the primary organizers of such efforts, networking progress can actually have a negative impact (Dobbin et al., 2011).

Overview

Several theories by sociologists have tried to explain why prejudice exists. Some emphasize economic concerns (the exploitation and scapegoating theories), whereas other approaches stress normative factors. No one explanation is sufficient. Surveys conducted in the United States over the past 60 years point to a reduction of prejudice as measured by the willingness to express stereotypes or maintain social distance. Survey data also show that many Whites and Blacks are still intolerant of each other. Prejudice involving Hispanic groups, Asian-Americans, and relatively large recent immigrant groups such as Arab Americans and Muslim Americans is well documented. Issues such as immigration and affirmative action reemerge and cause bitter resentment. Furthermore, ill feelings exist among subordinate groups in schools, in the streets, and in the workplace.

Equal-status contact may reduce hostility among groups. However, in a highly segregated society defined by inequality, such opportunities are not typical. The mass media and workplace diversity programs can be of value in reducing discrimination but have not done enough and may even intensify ill feeling by promoting stereotypical images. While strides are being made in increasing the appearance of minorities in positive roles in television and films, one would not realize how diverse our society is by sampling advertisements, programs, or movie theaters.

Abstract

The frontal lobe of primates consists of two large regions, a rostral region involved in cognitive functions (prefrontal lobe) and a caudal region mostly devoted to motor functions (agranular frontal cortex). This last region is formed, posteriorly, by the primary motor cortex and, anteriorly, by a mosaic of distinct areas called premotor areas. Premotor areas can be subdivided into two main classes: caudal premotor areas and rostral premotor areas. The caudal premotor areas elaborate sensory information for action. The rostral premotor areas appear to play a control role on the caudal areas, relaying to them information from the prefrontal and cingulate cortex on individuals' motivation and long-term plans. In this way, potential motor actions formed in the caudal premotor areas can be executed or not according to the individual's needs.

The frontal lobe of primates is formed by two large regions: a rostral region involved in cognitive functions, called prefrontal lobe (*see* Prefrontal Cortex Development and Development of Cognitive Function), and a caudal one mostly devoted to motor functions. Histologically, the caudal region is characterized by the absence of granular cells. It is also referred to as the agranular frontal cortex.

The agranular frontal cortex consists of two main sectors: area 4 (the primary motor cortex) and area 6. Area 6 is neither anatomically nor functionally unitary, but is formed by a *mosaic* of distinct areas (see Picard and Strick, 2001; Rizzolatti and Luppino, 2001). In the present article, we will review the general organization of the premotor areas in monkeys and discuss in detail the operations of one of them. A short comparison between the monkey and human premotor cortex will be made in the last section.

Classes of Premotor Areas and Their Cortical Connections

The agranular frontal cortex is formed by seven distinct areas (areas F1–F7, see **Figure 1**). Area F1 corresponds to the Brodmann area 4 (the 'primary motor cortex') (*see* Motor Cortex);

Figure 1 Mesial (top) and lateral (bottom) views of the macaque brain showing the subdivision of the agranular frontal and posterior parietal cortex. The arcuate, cingulate, and intraparietal sulci are drawn unfolded to show the areas buried within their banks. For the nomenclatures and definition of the areas, see text. Abbreviations: AI = inferior arcuate sulcus; AS = superior arcuate sulcus; C = central sulcus; Ca = calcarine fissure; Cg = cingulate sulcus; IO = inferior occipital sulcus; IP = intraparietal sulcus; L = lateral fissure; Lu = lunate sulcus; P = principal sulcus; PO = parieto-occipital sulcus; ST = superior temporal sulcus.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.55046-6

the other areas are located within the Brodmann area 6. They are referred to as 'premotor areas.' Recently, one of them – area F5 – has been found to be formed by three distinct sectors: F5a, F5c, and F5p (**Figure 1**).

Each premotor area has a specific pattern of anatomical connections. According to the characteristics of to this pattern, the premotor areas can be subdivided into two main classes: the caudal and the rostral premotor areas (Rizzolatti and Luppino, 2001). The caudal premotor areas are *F2*, *F3*, *F4*, *F5p*, and *F5c*, while the rostral ones are *F5a*, *F6*, and *F7*.

Connections with the Spinal Cord and Intrinsic Motor Connections

The organization of the corticospinal and corticobulbar projections from the premotor areas is consistent with their subdivision into two classes. The corticospinal projections originate, besides the primary motor area, from those sectors of the *caudal* premotor areas where forelimb, trunk, or hind-limb movements are represented (see He et al., 1993). The sectors of these areas where face/mouth movements are represented are the source of corticobulbar projections targeting the facial nucleus (see Morecraft et al., 2001). It is interesting to note that F2, F3, F4, F5p, and F5c display somatotopically organized connections with F1, as well as, with each other. These data indicate that although F1 is the only area with direct access to the spinal cord motor neurons, the caudal premotor areas have also access to the spinal cord. Thus, these areas can be involved in the generation and control of movements both trough F1 or in parallel with its output.

The organization of the rostral premotor areas is radically different. These areas do not project to the spinal cord, their descending input terminating in various parts of the brain stem. Furthermore, the rostral premotor areas are not connected with F1 and, especially in the case of F6, have widespread connections with other motor areas. An exception is the dorso-rostral part of F7, corresponding to the supplementary eye field (SEF), which has very poor connections with other motor areas, but is strongly connected with the frontal eye field (FEF). These data indicate that the rostral premotor areas are involved in the generation of motor behavior only indirectly, through their subcortical relays or their connections with the caudal premotor areas.

Connections with Parietal, Prefrontal, and Cingulate Areas

The connections with the *parietal cortex* are the major source of input to the agranular frontal cortex and especially to caudal premotor areas and area F1. Similar to the premotor region the posterior parietal cortex is also formed by a mosaic of distinct areas (**Figure 1**). Each of them deals with specific aspects of sensory information and with the control of specific effectors. Note that the classical distinction between inferior parietal lobule (IPL), related to both visual and somatosensory information, and superior parietal lobule (SPL), exclusively related to the somatosensory modalities, is incorrect. Both IPL and SPL receive somatosensory and visual input.

Studies on the organization of the parietofrontal connections indicate that premotor and parietal areas are connected with each other in a very specific way (Rizzolatti et al., 1998). Accordingly, it is possible to identify a series of anatomical circuits formed by parietal and motor areas linked one to another by predominant connections. In general, these circuits connect SPL with dorsal and mesial premotor areas and IPL with ventral premotor areas. Functional evidence, when available, indicates that parietal and frontal areas forming each of these circuits share common functional properties. Therefore, the functional correlate of this anatomical organization is that each of these circuits is involved into particular aspects of sensory motor transformations. The essence of this operation is the transformation of a description of the stimuli in sensory terms into their description in motor terms. Thus, these parietofrontal circuits, and not the frontal motor areas in isolation, should be considered the functional units of the cortical motor system (Rizzolatti et al. 1998).

Prefrontal projections to the motor cortex are primarily directed to rostral premotor areas (Rizzolatti and Luppino, 2001; Gerbella et al., 2011). Prefrontal input to F7 (except for the SEF) originates from the dorsal part of the lateral prefrontal cortex (DLPF), that to F6 and the SEF originates from both DLPF and the ventral (VLPF) part of the lateral prefrontal cortex, and, finally, that to F5a originates only from the VLPF. In addition, F6 and the SEF are also the targets of strong afferents originating from the rostral cingulate cortex (area 24c). Cingulate connections to F7 and F5a are considerably weaker, while F5a is densely connected with rostral opercular frontal areas.

Our knowledge of the organization of the prefrontal and cingulate cortex is much less detailed than that of the parietal cortex. It is, however, widely accepted that these regions are not involved in the mere analysis of sensory stimuli, but rather play a role in 'higher order' functions such as working memory, temporal planning of actions, and motivation. These data indicate that caudal and rostral premotor areas play a different functional role in motor control. Caudal premotor areas, together with parietal areas, are involved in transformation of sensory information into potential motor actions. Rostral premotor areas appear to play a hierarchically higher role. These areas receive information concerning agent's goals, motivation, and memorized spatial and nonspatial information from the prefrontal, cingulate, and opercular frontal cortex. This information is then conveyed to the caudal premotor areas determining when and which potential actions, coded in these areas, might become actual actions.

Functional Organization of the Premotor Areas

To illustrate the information processing carried out in the premotor cortex, we will describe the activity of an area (area F5) in detail. As far as the other premotor areas are concerned only their fundamental properties will be reviewed.

Area F5

Area F5 occupies the rostroventral part of the agranular frontal cortex (**Figure 1**). Its electrical stimulation evokes hand and mouth movements. The firing of neurons in F5 correlates with specific motor acts (e.g., grasping) or segments of them (e.g., hand opening, hand closure during grasping) rather than with

the individual movements that form a motor act. Grasping, holding, tearing, and manipulating are the motor acts most represented.

F5 was originally described as a single entity. Recent multiarchitectonic data showed that F5 is not homogeneous but formed by three discrete sectors (Belmalih et al., 2009). One of them, designated as F5 'convexity' (F5c), is located on the convexity of the postarcuate cortex adjacent to the inferior arcuate sulcus. The other two, dubbed as 'posterior' and 'anterior' F5 (F5p and F5a, respectively), lie within the postarcuate bank at different anteroposterior levels (**Figure 1**).

F5c is a motor field related to hand, face, and mouth actions. A substantial proportion (about 20%) of its neurons form a particular class of visuomotor neurons, called *mirror neurons* (see Rizzolatti and Craighero, 2004). The distinctive feature of these neurons is that they discharge *both* when the monkey *observes* another individual (a human being or another monkey) performing a hand or mouth action and when it *executes* the same or a similar action. Mirror neurons do not discharge in response to the simple presentation of food or other objects of interest to the monkey.

The fundamental function of mirror neurons of F5 is that of transforming observed actions, done by others, into corresponding motor representations in the brain of the observer. By eliciting these motor representations, which are identical to those that the observer uses to produce voluntary movements, mirror neurons allow the observer to understand what the agent is doing.

It may sound bizarre that in order to understand an action done by another, one should activate the motor system. Actually, this is not so strange. A mere visual perception, without involvement the motor system only provides a description of the visible aspects of the movements. It does not give information on what really implies doing it, on the links between the observed actions and other actions related to them or on how to imitate it. This can be achieved only if the observed action is mapped onto the motor system of the observer. Thus, the activation of the mirror neurons is essential to provide the observer with an 'experiential' comprehension of the observed action.

There is evidence that, especially in humans, besides action understanding the mirror mechanism is involved also in other cognitive functions like imitation.

F5c is connected with area SII and areas AIP and PFG located in the IPL. These last areas are, in turn, richly connected with sectors of the superior temporal sulcus (STS) known to code complex motor acts (Perrett et al., 1989). Mirror neurons have been found in both areas PFG and AIP, while neurons of STS appear to be devoid of motor properties.

Other studies have evidenced that neurons of F5c are involved in the evaluation and comparison of current and remembered sensory information for perceptual decisions (Lemus et al., 2009) and in the evaluation of the outcomes of these decisions for organizing future behavior.

F5p is essentially a hand motor field, encoding specific goal-directed motor acts. A proportion of F5p neurons are responsive to the observation of 3D objects ('canonical' neurons, see Rizzolatti and Luppino, 2001). These neurons are involved in the selection of hand motor acts appropriate for object interactions based on the object physical characteristics (Jeannerod et al., 1995). F5p is tightly connected with the hand field of the primary motor area. These connections enable F5p to generate object-oriented hand actions through the modulation of motor output of primary motor cortex (Prabhu et al., 2009). F5p also project to the brain stem and to the cervical spinal cord. This suggests a direct role of this area in the execution of hand motor acts.

As F5c, F5p is densely connected with areas AIP, PFG, and SII. Area AIP is a hand-related field located in the rostral part of the lateral bank of the intraparietal sulcus. It contains a large number of neurons that discharge during the execution of specific grasping movements.

Sakata et al. (1995) subdivided the neurons of AIP into three groups: 'motor-dominant,' 'visual and motor,' and 'visual-dominant' neurons. About half of 'visual and motor' and 'visual-dominant' neurons discharge not only during grasping execution, but also when objects are simply fixated. In these neurons, the visual responses appear to reflect the intrinsic properties of the observed object. The other half of 'visual and motor' and 'visual-dominant' neurons is not active during the passive fixation of objects. These neurons fire in association with the observation of hand or hand/object interactions. Some of these neurons are mirror neurons.

AIP receives information on physical properties of the objects from the dorsal visual stream. Recently, it has been shown that AIP is also connected with the ventral bank of STS and the inferotemporal cortex (Borra et al., 2008; Nelissen et al., 2011). This last connection suggests that AIP has information on object semantics. Thus, AIP and F5p appear involved in visuomotor transformation for grasping based not only on the physical characteristics of the object but also on their meaning.

The third area heavily connected with F5c and F5p is area SII. This area, located in the parietal operculum, is a somatosensory area of higher order involved in tactile recognition of objects and in coding tactile expectancies about impending contact with objects. SII may provide F5 with tactile feedback or memory-based somatosensory expectations, instrumental for selection of grasping motor programs and/or the control of fingertip forces for grasping stability.

F5a has basically agranular structure, but some features proper of the granular frontal cortex. Among them, the presence, although moderate, of granular cells, the rather homogeneous and relatively prominent layer V, and the relatively low myelin content. F5a has some parietal connections similar to those of the other F5 sectors, but also show some features absent in those sectors. More specifically, F5a is the only sector of area F5 connected with ventrolateral prefrontal areas (area 12, and ventral 46). Furthermore, it displays connections with rostral opercular frontal sectors much stronger that those of the other F5 sectors.

Functionally, F5a has been less studied than the other sectors of area F5. However, on the basis of its connections, it is plausible that F5 is a site of integration of sensory motor signals originating from the parietal cortex with higher order information originating from prefrontal and frontal opercular areas. These last inputs could give F5p information on objects shapes, texture, and weight related to past experience as well as

information related to agent's intention. This integration could be instrumental for the generation and control of actions.

Caudal Premotor Areas (F2, F3, F4)

Area F2 forms the caudal part of the dorsal premotor cortex. Area F2 is electrically excitable and has a somatotopic organization with a leg and an arm representation located dorsal and ventral to the superior precentral dimple, respectively (Rizzolatti and Luppino, 2001). Functional studies of F2 have been mostly focused on its motor properties, by employing visually instructed motor delay tasks. Some F2 neurons discharge in association with movement onset (movement-related activity), others become active during the delay period when the monkey is waiting for the go signal (set-related activity), others discharge at the appearance of the instruction stimulus (signal-related activity). These data indicate that F2 is not simply involved in motor execution, but plays a role also in some aspects of motor preparation (Wise et al., 1997). Furthermore, F2 neurons appear to be involved in coding action instructions associated with a symbolic cue or retrieving motor instructions at an abstract level even when the location of actual motor targets is not yet available. Finally, there is evidence that F2 neurons activity can reflect covert mental rehearsal of arm reaching movements elicited by the mere observation of their sensory outcomes (see Rizzolatti and Kalaska, 2013).

F2 contains neurons predominantly responding to somatosensory and in particular proprioceptive stimuli. It receives predominant projections from areas PEc and PEip. However, the ventro-rostral part of F2 hosts neurons responding to visual stimulation and is predominantly connected with areas MIP and V6A.

All the various parietal areas connected to F2 host neurons active during the execution of arm-reaching movements. They are considered to be part of a parietofrontal system crucially involved in the sensory guidance of arm reaching movements. There is evidence that in MIP and V6A there are neurons responsive to both visual and somatosensory stimuli. V6A also contains neurons related to the execution of wrist and hand movements, suggesting a role of V6A-F2 (ventro-rostral part) circuit in the control of reaching to grasp movements.

Area F3 (or SMA proper) is located on the mesial surface of the agranular frontal cortex (**Figure 1**). Its main input originates from somatosensory parietal areas (mostly mesial area PE). F3 contains a complete representation of body movements, with a prevalence of proximal, arm and leg, and axial movements. Electrical stimulation of F3 frequently evokes complex movements, involving both proximal and distal joints. Single joint movements are rarely evoked (Luppino et al., 1991). Neurons of F3 fire in association with active movements.

It has been proposed that F3 encodes limb position in order to set the posture for the incoming movements. According to this view, F3 plays a fundamental role in *predictive* postural adjustments. Some neurons of F3 were found to fire in relation to specific sequences of movements. It has been, therefore, suggested that F3 is involved in sequential organization of learned multiple movements (Tanji, 2001).

Area F4 forms the caudal part of PMv. Its electrical stimulation elicits arm, neck, face, and mouth movements (Gentilucci et al., 1988). Head avoidance, as in the presence of threatening stimuli, has been also described (Graziano, 2006). Neurons of F4 become active during the execution of goal-directed motor acts, such as reaching for food or bringing it to the mouth, others discharge during oro-facial movements. Based on their sensory responses, F4 neurons can be subdivided into two categories: unimodal (mostly tactile) neurons and bimodal (visual and tactile) neurons (Fogassi et al., 1996). In both categories, tactile receptive fields (RFs) are rather large and predominantly located on the face, arm, and the upper part of the body. Bimodal neurons have three-dimensional visual RFs in register with the tactile fields and limited to the space around the body (peripersonal or reaching space). In most of these neurons, the position of the visual RFs does not change when the gaze or the body part, where the tactile RFs is located, moves. These neurons play a fundamental role in transforming the position of objects located in the peripersonal space into appropriate motor acts directed toward or away those objects (Fogassi et al. 1996).

F4 is tightly connected with areas PF and VIP of IPL (**Figure 1**). Area PF is a possible source of somatosensory input related to the face and the mouth (Rozzi et al., 2008). Area VIP is the target of dorsal visual stream areas involved in the analysis of motion perception (e.g., MT, MST, FST) and of somatosensory areas (see Colby, 1998; Rizzolatti et al. 1998). This area hosts visual neurons and bimodal (visual and tactile) neurons displaying functional properties similar to those of bimodal F4 neurons (see Colby, 1998). Area VIP represents, therefore, an initial step in the elaboration of visual information for building the peripersonal space (Rizzolatti et al., 1997, 1998; Colby, 1998).

Rostral Premotor Areas (F6, F7)

Area F6 (or pre-SMA) is located rostral to F3 on the mesial sector of the agranular frontal cortex. It corresponds to the anterior part of the classical SMA described by Woolsey and Penfield. Motor responses can be evoked from it only with rather high current intensities. Typically, these responses consist of slow, rather complex arm movements (Luppino et al. 1991). Visual responses are common in F6, while somatosensory responses are rare. F6 neurons, recorded during active arm movements, show frequently a long leading activity preceding movements (Tanji, 1994).

Studies carried out in naturalistic conditions, where monkeys were allowed to interact with objects presented close to or far from them, showed that F6 neurons exert a global control on arm actions, rather than a control limited on specific, distal (like F5), or proximal (like F4) motor acts. Some neurons of F6 discharge at the presentation of graspable objects independent of their location, increasing their firing as the stimulus moves toward the monkey. Others, on the contrary, are inhibited at the presentation of the graspable objects, but start to discharge as soon as an object is brought close to the monkey. In short, there are several facilitation/inhibition combinations that characterize different F6 neurons. What appears to be constant is the modulation of the neuron discharge according to whether an object can or cannot be grasped (see Rizzolatti et al., 1998).

Recent data showed that F6 plays an important role in the early stages of motor learning, precisely when the cognitive

aspect of the procedure to be learned is acquired. This conclusion is based on the behavior of single neurons and on inactivation experiments showing that the number of errors for learning new sequences increases after muscimol (a selective $GABA_A$ agonist) injections in F6. In contrast, the performance of already learned sequences is not affected by F6 (Hikosaka et al., 1999).

Summing up, F6 appears to play a double role in motor control. First, it controls the activity of the posterior premotor areas. Normally, even when the posterior areas are activated, movement does not start. Only when external contingencies and motivational factors allow it, the movement occurs. F6 is the area that renders the movement onset possible. A second role of F6 is more cognitive. It consists in the control of visuomotor associations underlying the declarative phase of motor learning.

Area F7 forms the rostral part of the PMd. Functionally area F7 is not homogeneous. The dorsal part of it is not related to motor control of body parts, but contains an oculomotor field, called the 'SEF.' Anatomically, the SEF is strongly connected with the FEF, but is also the target of strong projections from both dorsal and ventral areas of the lateral prefrontal cortex. Furthermore, the SEF receives afferents from the rostral cingulate cortex. These anatomical data suggest that the SEF could be involved in the control of eye movements at a higher hierarchical level than the FEF. In line with this hypothesis are functional data showing that the SEF is involved in encoding saccades relative to an object-centered frame of reference (Olson and Gettner, 1995) as well as in monitoring the consequences of eye movements (Stuphorn et al., 2000).

The remaining part of F7 has been the target of relatively few functional studies. Some F7 neurons show visual responses even when the stimulus is not instructing a subsequent movement. Others show visual responses when the location of the stimulus matches the target of the arm movement (Vaadia et al., 1986).

F7 receives strong projections from dorsal area 46 and area 8b of the prefrontal cortex (Luppino et al., 1993), i.e., from areas involved in the working memory of spatial positions. Minor inputs to F7 originate from parietal areas PGm and V6A (Matelli et al., 1998). These data could be at the basis of the possible functional role of F7-non SEF in coding locations of sensory stimuli, or arbitrary sensory information, for the guidance of arm movements. This role is suggested by results showing that neurons in this area are related to eye and arm movements (Fujii et al., 2000), are involved in coding spatial localization of external stimuli for reaching movements (Vaadia et al., 1986), and have visual responses, even when the stimulus is not instructing a subsequent movement (di Pellegrino and Wise, 1991). Lesions including F7-non SEF and F2vr (both targets of DLPFd) severely affect the performance of the animal in previously learned motor association tasks and prevent new learning (see Passingham, 1993).

The Premotor Cortex of Humans

As in the monkey, the premotor cortex of humans is formed by a series of distinct areas, some located on the mesial wall of the frontal lobe, others on its convexity.

The large supplementary motor cortex described by Penfield and Woolsey has been found to be formed by two anatomically and functionally distinct areas: area SMA proper and pre-SMA. Functionally, they are considered to be the homologues of monkey area F3 and area F6, respectively. The fMRI data indicate that in both monkeys and humans, the border between the two medial areas is located at the stereotaxic level AP = 0.

The dorsolateral part of the human premotor cortex is formed by two major sectors: the dorsal (PMd) and ventral (PMv) premotor cortex. Unlike in the monkey, an anatomical marker separating PMd from PMv is absent in humans. However, on the basis of embryological data and on location of the FEF it has been suggested that the border between human PMd and PMv should lie approximately at Z level 50 in Talairach coordinates (Rizzolatti et al., 2002). This border has been recently confirmed by diffuse tensor imaging studies (Tomassini et al., 2007).

There is evidence for a rostro-caudal heterogeneity of PMd that most likely parallel the monkey subdivision. In fact, fMRI studies showed that movement tasks activate the caudal sector of PMd, while more cognitively demanding tasks tends to activate its rostral sector.

A large number of brain imaging studies showed that PMv contains the mirror mechanism. Mirror responses were found in PMv but they also to extend rostrally in the posterior part of the inferior frontal gyrus. Some studies reported mirror responses also in PMd.

Although, it is very likely that human PMv, as that of the monkey, is formed by different areas, a clear, consistent parcellation of human PMv has not yet been established. Similarly, the issue of what might be the monkey homologue of area 44 is matter of debate.

In conclusion, the comparison of human and monkey premotor regions clearly indicate that the basic functional organization of this region has been maintained in evolution. The most dramatic modifications have been those due to the appearance of speech and related evolution of areas mediating this function.

Abstract

Section Overview of this article provides an overview of milestones in prenatal and infant development (from conception through 2 years of age and the emergence of language). Section Current Trends discusses current trends in the field with emphases on newer theories (e.g., dynamic system theories) and research, notably on the 'ecologies of infancy' (diversity of prenatal and infant development including the influences of culture and socioeconomic status, the effects of parenting, and nonparental care of infants) and on neurological brain assessments of infants. Section Future Directions concludes with consideration of future directions for the development of an integrated infant science.

Overview

Since 1980 the pace of new scientific knowledge about prenatal and infant development has increased sharply, yielding a picture of an organism actively engaged in extracting information from and interacting with the world. Even the fetus is responsive to stimulation in all sensory modalities and has the capability of learning – a capacity that expands in new and increasingly sophisticated ways after birth. The effects of early experiences are both cumulative and enduring throughout infancy (*see* Human Development, Theories of). Studies with prenates have revealed that neurally mediated behavior following birth is continuous with behavior during the prenatal period, finally shifting from principally subcortical to increasingly cortical control between 2 and 4 months of age. This shift ushers in a rapid increase in social and other learned behaviors that, in relatively short order, will position the infant on the threshold of childhood, armed with the motoric, social, and cognitive tools necessary to cross over. Thus, this article considers the mileposts of the organism's prenatal and postnatal achievements, recent theory and research, and future prospects for prenatal and infant science.

Infancy extends from birth to 2 years of age. It has long been regarded as a special period of life in which numerous important transformations of structure take place, and the essential processes of information exchange with the world are laid down. Over this period, the infant is transformed from a condition of utter dependence on the caregiver for survival to a condition of relative independence or life-preserving agency – a transformation accompanied by marked physical, cognitive, and behavioral changes. While no characterization of this transition is entirely satisfactory, several elements set the infant apart from children of other ages. Despite disclaimers that what happens very early in life can be reversed or improved upon, most developmental psychologists celebrate the very considerable and enduring influence of early experience (*see* Infancy and Childhood: Emotional Development; Socialization in Infancy and Childhood). The following section paints a broad picture of infant development, its prenatal antecedents, and its relation to the behavior of older children and adults.

Prenatal Development

Physical and Cognitive Development

The 'prenatal period' extends from conception to birth. During the 'germinal stage' (fertilization–2 weeks) and 'embryonic stage' (2–8 weeks), the fertilized egg rapidly divides and attaches to the uterine wall, the major organs and systems of the body differentiate, and interconnections form between the developing components of the central and peripheral nervous systems. During the fetal stage (8 weeks–birth), the organism grows rapidly and the physical features that are identified as human become increasingly apparent.

During the prenatal period, the mechanisms that will facilitate the organism's adaptation postnatally become functionally mature. Infants born prematurely, for example, who readily learn responses that increase the amount of quiet sleep, reveal this anticipatory maturation. The characteristics of the mother's voice are also learned during the prenatal period. After birth, hungry infants orient and root in the direction of their mother's voice, thereby increasing their efficiency of breastfeeding irrespective of whether the mother is holding them on her left or right side. Newborns will also learn to activate a tape recording of their mother's voice – but not of another woman's voice – by sucking nonnutritively on a modified nipple. Moreover, 'prenatal learning' is highly specific: newborns will suck harder to listen to their mother reading a Dr Seuss passage that she had read aloud daily during the last 6 weeks of gestation than to hear her reading a novel Dr Seuss passage (DeCasper and Spence, 1986). This specificity continues postnatally throughout the first half-year. Similar learning prenatally familiarizes organisms with the linguistic environment into which eventually they will be born.

The Jacksonian Principle

The development and dissolution of prenatal motor function is described by the 'Jacksonian principle,' which states that the

[†] Deceased.

last reflexes to develop are the first to disappear when the organism undergoes demise, whereas the first to develop are the last to disappear (Jackson, 1884, cited in Taylor, 1958). The contralateral (avoiding) reflex, which moves a stimulated site away from a tactile stimulus, is supplanted weeks later by an ipsilateral reflex (Hooker, 1952). This sequence is reversed by fetal anoxia. The reversion occurs because reflexes which develop first are well practiced and require less oxygen to be initiated than more recently developed reflexes. Similarly, the order in which sensory functions develop (tactile, vestibular, thermal, chemical, auditory, and visual) is subsequently reversed during injury, disease, or aging.

Mileposts of Infant Development

From 0 to 6 Months

Birth marks the organism's transition from a parasitic, waterborne existence in a thermally constant environment with constant access to nutrition to an independent, land-dwelling existence in a desiccating and cold environment with discontinuous access to food. The occasion of birth involves a transition important primarily for triggering the onset of the 'regulatory mechanisms' (respiration, blood flow, digestion) critical for this transition. These regulatory arrangements and their interactions are the major constraints on the newborn's behavior and the environmental conditions it can tolerate (Adolph, 1968). The evolutionary requirement of all newborn mammals is to grow, which necessitates maximizing energy intake and minimizing energy expenditure (*see* Lifespan Development: Evolutionary Perspectives). Not surprisingly, therefore, newborns primarily eat and sleep. Early postnatal learning also reflects this necessity: newborns readily learn where and when food is accessible. Also, because full-term newborns do not physiologically thermoregulate before 4–9 weeks of age, they do not require energetically costly responses which can compete with behavioral thermoregulation.

Over the first 3 months of life, the birth weight of the infant doubles. During this period, brain development is very rapid and influenced appreciably by the kinds of experience to which the infant has been subjected. While most information about dendrite proliferation, the directionality of neuronal connections, cell death, and the effects of deprivation on neural and behavioral development comes from mammals other than humans, the universality of the effects described by neuroanatomists and neuropsychologists is impressive.

In the period following birth, much of the infant's behavior is reflexive, that is, specific stimuli call forth specific reactions (e.g., touches to the mouth elicit rooting and mouthing, abrasions of the skin elicit retraction of the injured body part). This early behavior is principally under the control of the subcortical portions of the brain, and the elicited behaviors are typically swift and obligatory.

Between 2 and 4 months of age, cortical maturation – especially dendritic proliferation – is increasingly evident, and neonatal reflexes disappear or weaken. Also during this period, activity undergoes a major transition from elicited to voluntary. The developmental sequence in which reflexes emerged during the prenatal period is recapitulated during this transitional period, and the sequence in which the postnatal reflexes appear is similarly reversed when the organism is challenged (Humphrey, 1969). The postnatal repetition of fetal activity sequences is again due to the lower oxygen requirement of more primitive, hence more practiced, reflexes. Practicing neonatal reflexes reduces their oxygen requirement and speeds the transition.

The transitional process has been implicated in the 'sudden infant death syndrome' (SIDS). McGraw (1943) characterized the period when reflexes are neither reliably elicited nor under voluntary control as a period of 'disorganized behavior.' The transitional period of the respiratory occlusion reflex corresponds to the time when SIDS is most likely to occur (95% of all SIDS or 'crib death' cases occur between 2–5 months). By 6 months, the occlusion reflex has come under cortically mediated voluntary control, and the infant is once again able to defend successfully against respiratory occlusion (Lipsitt, 1979, 2003; *see* Infant and Child Mortality in Industrialized Countries). Also, over the first 3 months of life, the behavioral repertoire of the infant sharply expands.

Infants can acquire both classically conditioned and operantly conditioned responses at birth and can remember what they have learned for a surprisingly long time (Lipsitt, 1969). An eyeblink reflex that is classically conditioned at 10 days of age, for example, is remembered for at least 10 days. Newborns can habituate to a repeatedly presented stimulus and discriminate it from others that they have not previously encountered. Imitation, a particularly efficient form of learning, can be demonstrated within hours of birth. Not only can newborns imitate an adult's facial gestures immediately after they are modeled but, by 6 weeks of age, infants can imitate facial gestures after a 24-h delay. Piaget (1962) described early facial imitation as stimulus-bound and reflexive and hypothesized that it disappeared along with many other neonatal reflexes. However, it was later shown not to disappear (e.g., Meltzoff and Moore, 1994). Infants' early imitation of facial expressions foreshadows their later dyadic interactions with adults and siblings.

By 3 months of age, infants can acquire arbitrary categories, learn the serial order of an arbitrary list, and pick up incidental information about events in their visual surround – including information about correlated features ('what goes with what'). Although some aspects of visual processing (e.g., accommodation and convergence, and feature search) are adultlike by 3–4 months, others (e.g., visual acuity and conjunction search) do not achieve adult levels for 1 year. Infants can detect depth by 2–3 months but do not fear depth until they begin to crawl. They can also recognize faces of live adults after 24 h by 6 weeks of age and can recognize them from photos by 5 months.

Observers often remark that infants blossom into 'social creatures' between 2 and 4 months of age, cooing and smiling widely at individuals who interact with them, reaching to other persons, and intensely watching the behavior of others. By their fourth month, infants follow conversations between adults with their eyes, differentiate social from nonsocial objects (which they previously did not), and imitate vocalizations. Not surprisingly, social stimuli are highly effective in establishing and maintaining behavior at this time. The features that define a stimulus as social, however, change with age. Although newborns differentiate between facial expressions and prefer to look at faces than at other visual stimuli, this preference is not based on a social dimension but on contrast and movement – critical features of the human face

that influence infants' scanning patterns over the first 8 weeks. By 4 weeks of age, however, infants display greater pupillary dilation to social than nonsocial stimuli; by 6 weeks, they display differential cardiac responses to mothers and strangers; and by 12 weeks, they display differential pupillary responses to them and smile more frequently at the mother than at a stranger.

From 6 to 12 Months

During the second half-year, a normal infant becomes a walker, a speaker, and a social being who responds emotionally to parents and differentially to familiar persons and strangers. The simultaneous appearance of strong attachment to caregivers and wariness of unfamiliar individuals at 9–10 months of age is one of the most consistent benchmarks of this period (Ainsworth, 1979). At the same time, infants begin to look at the target of a pointing finger rather than at the finger per se and begin to exhibit social referencing – a strategy by which infants assess the emotional valence of a new situation or person by checking how the caregiver has responded and responding in kind.

For a half-century, another developmental benchmark was attainment at 10 months of object permanence – the concept that an unseen object or person continues to exist. In the classic object search task, infants younger than 10 months consistently failed to retrieve an object they had just watched an adult hide. New paradigms using looking instead of reaching measures, however, have now revealed that even 3-month-old infants can locate where an object was hidden.

The types of learning of which infants are capable and their understanding of the physical world rapidly expand over the last half-year. Infants can individuate objects, solve problems requiring causal reasoning, form learning sets ('learning how to learn'), comprehend some spoken speech, repeat a couple of syllables and perhaps produce a word, plan and execute a detour, and track objects through occlusion – a finding that has fueled heated debate over whether infants can count. Before infants begin to crawl (7–9 months), they have already learned what happens in what places. Once infants can locomote, they begin to form a cognitive map or representation of the spatial relationships between these places, which facilitates navigation from one place to another.

From 12 to 24 Months

Over this period, infants' linguistic, motoric, and cognitive skills continue to improve and broaden. Between 12 and 18 months of age, for example, infants can use landmarks to locate objects instead of using their own body as a reference point and, between 18 and 24 months, they can use geometric cues in the environment to reorient. Although 18 months was set as the minimum age for deferred imitation of actions on an object (Piaget, 1962), the use of tasks particularly suited to younger infants has lowered this age to 6 months. Still, infants' ability to imitate televised demonstrations lags well behind their ability to imitate live demonstrations. The same live demonstration that 6-month-old infants can imitate after 24 h cannot be imitated from television before 18 months, although 15-month-old infants can imitate some televised actions after 24 h if the viewing conditions are more naturalistic. Generally speaking, the pervasiveness of reports that infants' cognitive and motoric performance is superior in natural settings calls into question most if not all minimum age limits that have been imposed by laboratory tests.

Within the last 5 years, research on the ontogeny of memory has revealed that retention increases linearly over the infancy period, and reminders protract retention even longer. At all ages, a single reactivation or reinstatement reminder, for example, doubles the life of a memory – a remarkable result given that memories of older infants are initially so long. The finding that a few reinstatements can maintain a memory acquired at 6 months through 2 years of age reveals that early experiences can be enduring and raises new questions about infantile amnesia (adults' inability to recollect experiences from early childhood). The two memory systems (declarative, nondeclarative) found in older children and normal adults are also functional by 3 months (Rovee-Collier et al., 2001).

Risk Factors and Individual Differences

In recent years, advances in the successful delivery and survival of very small and premature babies, often born in jeopardy, have fueled new debate over the importance of early experience. Because the lower threshold for survival is very new, it is inevitable that time must pass before the numerous longitudinal studies, now under way, will yield critical information about the relation between specific prenatal deficits and neonatal hazards, on the one hand, and particular developmental outcomes, on the other. Such investigations are unlikely to rule out the possibility that some affected infants will be indistinguishable from their age-matched peers in developmental competencies. It is a question of proportions and resiliency.

Although infants born 38 weeks after conception are, on average, less mature than those born at 40 weeks are, the level of physiological maturity can vary among infants born at 40 weeks by as much as 3–4 weeks. Sex differences are also present at birth, with girls being 1–2 weeks ahead of boys in neurological maturation. In normal infants, some of this variability disappears by the end of the first year, but many individual differences persist, the full range and significance of which are not yet fully appreciated.

Early attempts to predict later intellectual performance from infant behavior focused on sensory and motor abilities and were unsuccessful. Modest-to-good correlations have now been found between measures of information processing beginning at 5–6 months (e.g., habituation rate, novelty preference, 1-week retention ratios) and scores on various intelligence tests at 3–5 years. The Fagan Test of Infant Intelligence (Fagan and Detterman, 1992), which correlates later intelligence with infant novelty preference scores, is sensitive to early exposure to environmental toxins, substances of abuse, nutritional deficits and supplements, maternal HIV infection, intraventricular hemorrhage, bronchopulmonary dysplasia, genetic anomalies, and various neurological abnormalities.

Early Origins

The origins of research on infant development can be traced to baby diaries published by Darwin and Preyer in the late

nineteenth century (*see* Lifespan Development: Evolutionary Perspectives). Over the first half of the twentieth century, detailed diaries of their own children's behavior stimulated Morgan, Stern, Guillaume, Valentine, and Piaget to propose theoretical accounts of early cognitive development (Wallace et al., 1994). At the same time, Pavlov's seminal work spawned longitudinal studies of classical conditioning with infants in Russia and other Eastern Bloc countries. These early studies provided the first systematic data on infant learning and documented the sequential onset of sensory function from the age at which stimuli from different modalities became effective conditioned stimuli. During this period, Western researchers produced only scattered reports of infant conditioning and retention, emotional development, activity, and color vision.

In 1958, federal funding of a long-term prospective study of infant development ushered in the era of modern infancy research. Using sophisticated apparatus and innovative methods, researchers at 12 sites across the United States began systematically to document the infant's basic sensory and learning abilities. These initial inquiries sparked subsequent generations of research on all aspects of perceptual, cognitive, and behavioral development across the entire span of infancy. By the end of the twentieth century, a large amount of developmental data were amassed on infant attention, perception, cognition, motor skills, and the sequellae of many early risk conditions and prematurity such as poverty.

Current Trends

Theory

Dynamic Systems Theories

Given the complexity of the issues at hand, the last 20 years or so have seen changes in some of the theories in which infant developmentalists are interested. For example, many have turned to transactional approaches, which treat the "… person's behaving, including his most advanced knowings as activities not of himself alone, nor even primarily his, but as processes of the full situation of organism–environment" (Dewey and Bentley, 1949: p. 104). In perhaps the most general version of dynamic systems theory based on an elaboration and extension of Werner's (1957) comparative developmental theory (Demick, 2011), the organism (here, infant), the environment, and their respective aspects (the physical/biological, psychological/intrapersonal, and sociocultural aspects of the organism together with the physical, interorganismic, and sociocultural aspects of the environment) mutually define, and cannot be considered independent of, one another.

The implications of such conceptualization are far-reaching in that: (1) the appropriate unit of analysis becomes the infant-in-environment system whereby the infant is viewed as a system embedded in a variety of larger environmental systems; (2) a change in one aspect of the infant-in-environment system impacts the system as a whole, which is assumed to function in a state of dynamic equilibrium; (3) unidirectional socialization effects (parent-as-cause, child-as-effect) and bidirectional socialization effects (behaviors usually interpreted as the causes of correlated child behaviors may be parental reactions to children's constitutionally based traits such as temperament) are alternatively seen as transactional effects (infants and parents mutually and cumulatively impact one another in a continual process of development and change); and (4) by extension, infants' inherent characteristics are shaped by experience and this multidirectional influence of heredity and environment continues throughout life. Although there are subtle differences, others have termed theories employing such notions as 'systems,' 'ecological,' or 'contextual' theories.

Dynamic Systems Theory Applied to Infant Development

Some infant developmentalists now view development as dynamic insofar as the organization of the system as a whole changes as the infant matures and acquires new experiences; as one subsystem emerges, that change is accompanied by new experiences that influence and are influenced by comprehensive changes in related component systems (Thelen and Smith, 2006). For example, higher-level behavioral organization, development of self-produced locomotion, emerges from the coordination of the infant's component processes (visual–vestibular adaptation, visual attention, social referencing) and the change in a single process, self-produced locomotion, affects a wide array of his or her psychological skills (height perception, spatial localization of hidden objects, concept formation, emotional expression). Other developmentalists see inner biological factors as embedded in the individual, who is embedded in a family, embedded in a community, embedded in a culture. Thus, as the dynamics of a family change, changes in the relationship between parents, and between each of the parents and the infant, are also expected to change. The 'goodness-of-fit' or 'match' between infants and aspects of their developmental contexts also influence their long-term outcomes (Lerner et al., 2011).

Research

With the contemporary appearance of newer developmental theories with different emphases and/or of novel research methods (e.g., neurological assessment), the last 20 years have also seen changes in some of the research problems in which infant developmentalists are interested. The following represents a partial list.

Ecological Studies

As a function of the transactional approach and of ecological theories, infant researchers have more recently examined the many ecologies of infancy by posing at least four general research questions as follow (Bornstein et al., 2014; *see* Ecology of Aging).

- To what extent do parents' interactions with each other influence infant development?

Parents exert direct effects on their infants, for example, through heritability (cf epigenesis) and parenting (e.g., with infant physical, cognitive, and psychosocial competencies related to parental warmth, responsiveness, stimulation, and nonrestrictiveness; *see* Socialization in Infancy and Childhood). However, indirect effects (e.g., quality of parental relationships) can have just as significant impacts on infant development as direct effects. Supporting Bowlby's (1951) early observation,

when the relationship between parents is warm and supportive, parents are more attentive and sensitive to their infants. Paternal support has less effect on mothers (society expects mothers, regardless of their psychological states, to be devoted to the caretaking of their infants) than maternal support has on fathers (societal expectations of fathers' behavior toward infants are more varied, which impact their behaviors in marital relationships differentially). Partner support leads to more positive parenting quality especially when families are experiencing stressors (e.g., those associated with the transition to parenthood, difficult child temperament, financial hardship). Both younger and older motherhood present challenges to infant rearing. Young mothers are less responsive and attentive to their infants, this being related to less knowledge and realistic expectations about infant development as a consequence of less or poorer schooling; older mothers are often not prepared for the physical demands of infant rearing. Same-sex couples (lesbians more so than gay males, however) typically have experiences similar to heterosexual couples although this does not hold for single parents who must often deal with financial hardship and/or lack of social support. Poverty and economic failure are associated with punitive parenting, child abuse, and child neglect. Infants' exposure to domestic violence elevates their distress in response to conflict later in life.

- To what extent do sibling and peer interactions influence infant development?

Supporting Harlow's (1960) classic findings that infant monkeys learn how to play, fight, relate to, and communicate with others through peer interactions, older siblings engage in more assertive and directive behaviors than their younger siblings, including infants. With great interest, infants follow older siblings around, who in turn influence infants' cognitive and psychosocial skills through both direct teaching and modeling. There is remarkable stability across time in the extent of interaction between infants and their preschool age siblings. The quality of sibling relationships is also moderated by infant temperament (sociable infants receive more attention), sex (same-sex infants and siblings relate better than opposite-sex siblings), maternal management style (that fosters cooperation), parent–child relationships (securely attached infants exhibit less negative behavior when mother plays with siblings alone), and parent–parent relationships (positive parent–parent relationships lead to more prosocial and less aggressive sibling relationships).

Infant–peer relationships develop through a series of stages: (1) although very young babies exhibit an interest in peers, social interaction between infants is infrequent and unsustained during the first 6 months but becomes more complex from 6 to 12 months (including looks, smiles, vocalizations, imitation, and responsiveness to peer overtures but still with very little physical contact); (2) by 2 years, infants (who typically develop empathic and prosocial behavior between 12 and 18 months) no longer respond contagiously to their peers' emotions but rather observe their peers' emotions carefully and respond appropriately with prosocial (helping, giving) behaviors. Positive infant–peer relationships that continue into childhood are also moderated by family harmony and secure attachment to parents.

- To what extent does day care influence infant development?

Within the United States, 58% of married mothers of infants younger than 12 months work outside of the home (with higher rates for unmarried mothers and married mothers with infants older than 12 months). The rates are much lower in other countries because new mothers are often allowed paid leave from work for at least 1 year (vs 3 months in the United States). Nonetheless, longitudinal studies often subsidized by the governments of many countries indicate that high quality of care (characterized by adequate attention to each infant, encouragement of sensorimotor and language development, safeguards for health and safety, and warm, responsive professional caregivers) is crucial to infant development regardless of whether it takes place in a family day care or a center day care setting. In addition to the need for high-quality day care, its impact may vary from infant to infant with less difficulty exhibited by girls versus boys, by infants with easier versus more difficult temperaments, and by infants from families with more versus less income and education. Positive benefits of infant day care include infants' increased cognitive, language, and to a lesser extent social development as well as increased family finances and decreased parental depression, which are related to more adaptive children. Further, secure attachments to day care providers neither threaten nor displace secure attachments to parents. However, infant day care is detrimental when the mother is insensitive and the infant spends more than 20 h per week in a poor-quality program with too many children per group (NICHD Early Child Care Research Network, 2005).

- To what extent do socioeconomic status (SES) and culture influence infant development?

Fueled by changes in the demographic composition of our contemporary society, researchers have routinely begun to explore racial/ethnic differences in aspects of infant as well as child, adolescent, and adult development. The literature is thorny because investigators have often not differentiated between SES (typically based on education and occupation) and race/ethnicity (categorization of individuals based on outward appearance, which some have argued is merely a 'social construction' providing some with power because, e.g., dark-skinned people with African ancestry are more genetically diverse than light-skinned people with European ancestry). Thus, SES and race/ethnicity must routinely be considered independent factors that often interact with one another (cf Silva and Demick, 2013).

With respect to the surprisingly small number of studies on the influence of SES on infant development, researchers have replicated Labov's (1969) classic work documenting that, even though their infants are not yet talking, middle-class US mothers speak to them more (attempting to engage them in conversation to expand their communicative abilities) than lower-class mothers (who use more directives and corrections to foster compliant behavior). In line with this, there are also socioeconomic differences in maternal and paternal holding, maternal carrying, and paternal caregiving with extreme economic disadvantage leading to parents' decreased ability to respond effectively to their infants.

With respect to cultural differences, the motor skills (e.g., head control, limb extension, sitting, standing, walking) of infants in Uganda, for example, are more advanced than the motor skills of American infants, which is thought to be related to differential child rearing practices (whereby Ugandan mothers extensively carry their infants on cradleboards located on their backs so as not to interrupt their work or other daily chores, which in turn provides infants with increased vestibular, visual, and proprioceptive stimulation necessary for motor skill development). Further, some researchers (e.g., Bornstein, 2012) have interpreted cultural differences in terms of the now-classic distinction between functioning in individualistic versus collective societies, while others have generated complex models of the multidirectional route of many influences (social position variables, racism, segregation, promoting/inhibiting environments, adaptive culture, child characteristics, family) on minority children's development (e.g., Garcia Coll et al., 1996).

Studies of General Developmental Processes in Infancy: The Case of Body Representations

One area of recent interest to infant developmentalists is the early development of body representations. This research is the focus of the thirteenth installment in the *Cambridge Studies in Cognitive and Perceptual Development* series, edited by Hatano and Fischer. As the editors of this volume (Slaughter and Brownell, 2012) note, "Because we engage with the world and each other through our bodies and bodily movements, being able to represent one's own and others' bodies is fundamental to human perception, cognition and behavior. This edited book brings together, for the first time, developmental perspectives on the growth of body knowledge in infancy and early childhood and how it intersects with other aspects of perception and cognition …" (p. i).

This work is notable for several reasons. Although body image is one of the most widely researched constructs within psychology and related disciplines (Cash and Smolak, 2012), there has been little theoretical and/or empirical work on this problem by infant developmentalists. Thus, this work fills a much needed gap that will allow insights into body experience in infant development as well as into infant precursors of body experience development in children, adolescents, and adults.

Although the field of development is no longer dominated by monolithic theories, the contributions conform to Werner's (1957) cognitive-developmental analysis of body experience as developing first within the sensorimotor level (body action), then within the perceptual level (body perception), and finally within the conceptual level (body conception), all necessary precursors of the development of the next level, self-conception. Further, the organization – namely, the development of representations of the bodily self, of the bodies of others, and of the integration between self and other body representations – supports another of Werner's main themes of an increase in self-object differentiation with development. In these ways, this beginning work supports the generalization that there may be a synergistic relationship between grand developmental theories and problem areas previously unexplored (Demick, 2013).

This research area also has numerous implications. For example, early development of body representations helps us to understand better infant perception and representation of human form, imitation, understanding of biological motion, intentional understanding, action production, and self-representation. Most notably, the role of body representation for sensorimotor integration during visual perception also sheds light on its relationship to more general processes such as symbolic development. Further, in presenting appropriate theory to clarify terminology, this research sheds light on longstanding issues in infant development such as whether babies are born with or without a sense of self (broadly defined to include a bodily self). The proposed notion that infants possess a basic experiential, embodied self-unity at birth (body schema) but develop a more conceptual embodied self-unity (body image) over time can suggest that the newborn's body is for him or her, a differentiated entity among other entities in the environment (Dondi et al., 1999). Finally, in contrast to the qualitative methodologies typically employed in body image research on older individuals, the use of rigorous experimental methodologies appropriate for infants will ultimately help developmentalists assess the conditions under which cause–effect relationships in body-self interdependence occur in ontogenesis from its earliest beginnings.

Studies of Individual Differences in Infancy: The Case of Resilience

In line with the previous concern for individual differences (e.g., premature vs normal gestation infants), another hot-button topic for developmentalists in general is resilience, typically defined as "good outcomes in spite of threats to adaptation or development" (Masten, 2001: p. 228). Although this definition is clear enough, the construct of resilience has met both theoretical and methodological obstacles. Some researchers (e.g., Lipsitt and Demick, 2011, 2012) have acknowledged that the relationships among 'resilience' and earlier proposed constructs such as 'invulnerability,' 'stress resistance,' and 'protective factors' as well as the most efficacious way to measure resilience have been debated for some time but never resolved.

Lipsitt's (2003) work on SIDS as a biobehavioral phenomenon has direct applicability to the study of resilience in infancy. His approach assumes that the behavioral seeds of resilience inhere in the predisposing capabilities of the newborn infant. Viable human infants have reflexes, in some more intense than others, and these approach and avoidance behaviors are of lifesaving merit. The congenital reflexes of the newborn are 'coaxed' by environmental stimuli concordant with the growth of neuromyelin tissue and dendrite proliferation. 'Resilient infants' may be regarded as those in whom the migration to cortically mediated learned behavior from subcortical reflexes is successful, while nonresilient infants who succumb to SIDS during the critical 2- to 5-month period, when 90–95% of SIDS deaths occur, are those in whom the transition has been unsuccessful or incomplete. Nonresilient infants who succumb to SIDS during the critical 2- to 5-month period are those in whom the transition has been incomplete or unsuccessful. These nonresilient infants have not acquired the learned psychomotor strategies which, in resilient infants, can save the child's life from respiratory occlusion. Thus both researchers argue that future studies on resilience would be strengthened by investigations of antecedent–consequent

relations between prior adversities like familial violence and poverty, on the one hand, and later recovery or adaptation as mediated by a variety of coping strategies, on the other.

Lipsitt's discussion of the infant precursors of resilience sets the stage for Demick's (2014) contextual view of resilience in later stages of life as consisting of the individual's combination of the psychological traits of strength (e.g., hardiness, perseverance) and flexibility (e.g., mobility of cognitive style) with his or her capacity to shift back and forth between different subject–object conditions depending on the demands of the situation. Thus, both researchers argue that future studies on resilience would be strengthened by heightened laboratory investigations on antecedent–consequent relations between prior adversities (e.g., families, violence, poverty) and later recovery or adaptation as mediated by various coping strategies and fortuitous events.

Transdisciplinary Studies

Given the transdisciplinary nature of this encyclopedia, it is noteworthy that there are more and more research problems on which infant developmentalists and those in allied basic and applied professions are collaborating. Several of these are outlined below:

- Brain–behavior relationships in infant development

In the concluding section of our article in the first edition of this volume, we predicted that cognitive scientists and behavioral neuroscientists would soon join forces to relate developmental changes in infant cognition to specific changes in the developing brain, and that this effort would require the refinement of existing techniques and development of less invasive techniques for use with very young infants. We were correct on both counts.

Brain–behavior relationships in infant development have been assessed through the use of challenging methodologies that examine either infants' gross cortical electrical activity (measured by cortical event-related potentials, ERPs) or neurological anatomy (assessed by functional magnetic resonance imaging, fMRI). Use of these techniques is problematic because of cost and difficulty keeping infants in still positions. Nonetheless, based on these methods and the emerging evidence from them, it is clear that infants' memories are viable at very young ages and are capable of remarkable feats of deferred imitation and acting on goals established through previous experience, all in advance of presumptions from Piaget's (1962) important work on stages of development.

- Economics of infant development

Psychologists have joined forces with economists, political scientists, educators, and sociologists to collaborate on another problem of mutual interest, namely, the economics of infant development. Recent estimates suggest that a middle-class family can expect to spend over $15 000 simply bringing an infant from the hospital to a home equipped with the necessary supplies. A middle-class family can also expect that it will spend approximately another $225 000 for food, shelter, and other expenses (not including costs associated with college attendance and inflation). However, based on a cost–benefit analysis of early programming for pregnant mothers and young children relative to other social programs (e.g., increased numbers of high school personnel, adult job programming), Heckman (2006) argues that successful early intervention attempts like infant cognitive skill building, family support programs yield positive results such as lower adolescent pregnancy rates and less public assistance usage, and have a better rate of return. Such policy analyses of developmental data from other countries have also been conducted (e.g., Case et al., 2004).

- Parental development

Fueled by the publication of Bornstein's five-volume *Handbook of Parenting* and his initiation of a new journal *Parenting: Science and Practice*, researchers from a variety of disciplines (e.g., psychology, sociology, anthropology, medicine) have begun to explore the problem area of parental development. Although Bornstein's efforts have their origins in the emergence of ecological studies, investigators have taken a number of classical 'stage' theoretical approaches to this problem ranging from psychoanalytic theory (in the first stage, parents must relive and/or renegotiate their own oral conflicts when attempting to help their infants negotiate the same conflict) to cognitive-developmental theory (in the first stage, parents exhibit an 'egoistic orientation' and perceive their infants simply as projections of themselves) to sociological theory (the first stage, transition to parenthood, is a period of crisis for new parents that inevitably leads to decreased marital satisfaction). However, very few researchers have adopted transactional theories, which as noted have become increasingly popular and which led to Bornstein's new initiatives.

As exception, Demick (2002) argues that, whenever there is a perturbation to the person-in-environment system (e.g., cognitive disequilibrium in parents related to their infants' or children's behavior), parents must restore cognitive equilibrium to the system by reorganizing their self–world relationships. Such developmental processes occur with great frequency in transacting with one's infants or children on a daily basis. Although the particular issues posed by one's infants or children may change from one moment to the next (even if some appear with great regularity), parental reactions do not necessarily change. Parents are constantly faced with restoring cognitive equilibrium (or equilibrium to the person-in-environment system) in a dialectical process that they may experience similarly every time they are faced with a novel (or not so novel) stimulus from their infants or children. That is, parents are continually faced with attempting to return their differentiated and conflicted person-in-environment system states to more differentiated and integrated ones.

Future Directions

The next 20 years will witness extensive research that elaborates on present knowledge and which may challenge our current beliefs about infant development. Although advances have been made by cognitive and behavioral neuroscientists to relate developmental changes in infant cognition and, more recently, infant affect to specific changes in the developing brain, we again stress that our knowledge of infant brain–behavior relationships is still in its 'infancy.' New noninvasive techniques (e.g., similar to ERPs and fMRIs) are developed for use with very young infants. Methodological and technological advances should

also allow for new insights into prenatal development and its contribution to postnatal development.

Given the Zeitgeist that has contributed to making 'context' the buzzword for developmental psychologists and 'brain' the mantra for cognitive- and neuroscientists, future work should begin with these spirits of the time toward delineating and examining the structural and functional interrelationships between and among levels of organization (biological, psychological, sociocultural). Inroads into such conceptualization and research have already been made by some investigators.

Triggered by excitement surrounding the integration of previously independent lines of study (social developmental and neuroscience research), Bernier et al. (2012) have examined prospective links between quality of the infant caregiving environment and children's subsequent executive functioning (higher-order cognitive processes such as set-shifting, planning, and impulse control leading to successful goal-directed and self-regulated action, assumed located in the brain's frontal lobe). Given significant brain plasticity (whereby experience largely determines which synaptic connections persist or are pruned related to lack of use) and brain development (protracted postnatal development of the prefrontal cortex), the researchers assessed families on maternal interactive behavior, paternal interactive behavior, and child attachment security on three occasions (when infants were between 1 and 2 years of age) and child executive functioning on two occasions (at 2 and 3 years of age). They found that scores of parental behavior, including maternal sensitivity, maternal autonomy, and quality of father–infant interactions, as well as infant attachment status, are subsequently related to children's performance on executive functioning tasks (specifically, the exhibition of both strong cognitive flexibility and working memory). However, they also uncovered that infants' attachment status is the best predictor of their later executive functioning, leading to the conclusion that attachment security plays a meaningful role in the development of executive control. More studies such as this are sorely needed since they have the potential to advance theory, research, and practice as well as transdisciplinary collaboration.

Finally, before transdisciplinary collaboration might take place, researchers will benefit from comparing and contrasting the assumptions underlying their respective theoretical approaches. We are confident that the continuation of the strident pursuit of clarifying research on infant behavior and development, and the inevitable theoretical progress that will result, will reveal more subtle but profound commonalities from behavioral and dynamic system approaches (Lipsitt and Demick, 2012). We will not only become closer to understanding one another better but also to developing further the science of infancy in all of its real world complexity.

Multimedia

Center on the Developing Child at Harvard University: www.developingchild.harvard.edu. Designed to translate science into policy for multiple audiences including the public, this site contains multimedia materials mainly of interest to professionals and academics. Included are brief videos (e.g., 'In Brief: The Science of Neglect'), interactive features in the form of easy-to-follow slideshows on key concepts in early childhood development science (e.g., 'How Early Experiences Alter Gene Expression and Shape Development') and program evaluation (e.g., 'Early Childhood Program Evaluations: A Decision-Maker's Guide'), scientific publications, and working papers. The site also provides descriptions of the Center's initiatives including its National Scientific Council on the Developing Child and the National Forum on Early Childhood Policy and Programs.

Center on the Social and Emotional Foundations for Early Learning: http://csefel.vanderbilt.edu/resources/training_infant.html. This Vanderbilt University Center offers video infant/toddler training modules on promoting social and emotional competence. The modules are based on input about useful types and content of training from focus groups consisting of program administrators, early infant and childhood educators, and family members. All modules are designed to be consistent with evidence-based practices in the scientific literature. Each module comes with a PowerPoint presentation and all modules, including archived ones, are available in Spanish.

Centers for Disease Control and Prevention (CDC): http://www.cdc.gov/ncbddd/childdevelopment/positiveparenting/infants.html. This site contains multimedia materials for families, healthcare providers, and early childhood educators. For parents, there are videos (e.g., on how to look for developmental milestones) and Public Service Announcement (PSA) Video Kits on "Learn the Signs, Act Early" for them to distribute to local television and radio stations. For providers, the site supplies developmental screening tools and educational materials to provide to parents. For educators, there is a Childcare Provider Resource Kit including a CD-ROM with fact sheets and growth charts on child development for distribution to parents and posters for classroom display.

Education Portal: http://education-portal.com/academy/course/index.html. This Web site, which offers free college courses that may be transferred into accredited institutions, contains several lessons on Piaget's theory of cognitive development. Unlike many other online lessons that begin with Piaget's preoperational stage in early childhood, this site has a complete module on his sensorimotor stage of cognitive development that occurs in infancy with a focus on the construct of object permanence. This and other modules on Piaget (as well as all modules offered on this site) consist of written text, video, definitions, extensive examples, and a quiz (along with recommendations for other essential videos on infant development more generally). Although Piaget's theory has not been fully supported by research data, his work was groundbreaking particularly insofar as he provided us with an early glimpse into the mind of the infant.

Endowment for Human Development (EHD): www.ehd.org/movies.php. This is the official Web site of EHD, a nonprofit organization dedicated to improving health education and public health by equipping educators, clinicians, and governments with information to appreciate, apply, and communicate about the science of health and human development. The sight offers numerous selection of movies and videos on both normal and abnormal child development; some are free while others are available for purchase at low prices. The site also includes the best free video of the 'biology of prenatal development' that we were able to find on the net. The site also offers fact sheets (e.g., prenatal summary, prenatal time, prenatal overview), recommended readings on a variety of topics (including prenatal development), study guides, and a regular newsletter.

Head Start: An Office of the Administration for Children and Families Early Childhood Learning & Knowledge Center (ECLKC): https://eclkc.ohs.acf.hhs.gov. This Web site for Head Start, the best known early intervention program of its kind, provides a continually updated set of webcasts and videos for both lay and professional audiences. For example, the video 'Making Learning Meaningful' helps parents discover strategies for making learning relevant to children's everyday lives. The webinar 'A-133 Audit Training Webcast' aids professionals in understanding the importance of the annual program audit and the ways in which it can be used to strengthen an organization. Relevant here, there is an extensive collection of webcasts focusing on infants and toddlers from a description of Head Start's Family Child Care Program Option to those detailing lessons about infants, for example, building with blocks or playing with a ball. These latter broadcasts provide parents with information on what to expect from infants when they explore new materials as well as to help parents learn how simple activities may introduce infants to math and other concepts (e.g., exploration of the ball's roundness).

National Science Foundation (NSF): http://www.nsf.gov/news/special reports/science nation/babyface.jsp. This site highlights an NSF-funded study at the University of Miami on how infants' smiles provide clues to healthy development. An interdisciplinary team consisting of developmental scientists, machine vision experts, and face perception researchers are capturing on video cameras short structured playtimes between infants and their mothers. The videos are analyzed with a software program that registers and tracks the movements of the faces of the infants and their mothers as they interact in time toward illustrating the ways in which infants develop, for example, a sense of shared social emotion. In a companion study, the researchers are employing the same software program for examining the same types of interaction between mothers and their infants at risk for autism spectrum disorder (ASD) because they have an older sibling with a diagnosed ASD. Not only does this site describe funded research by one of our top scientific organizations but it also provides a video demonstrating the study's new software, which may transform how other questions about infant development are addressed.

Presidency, United States

John Hart, Australian National University, Canberra, ACT, Australia

Abstract

The study of the U.S. presidency has traditionally been broad in scope, disparate, eclectic, and unconstrained by fixed theoretical and conceptual frameworks. During the past 30 years' considerable introspection and self-criticism among presidency scholars have resulted in a more rigorous methodological approach to presidency scholarship and greater concern about its theoretical and conceptual underpinnings. No single approach dominates the political science of the U.S. presidency and current scholarship represents a mix of traditional and new approaches. In recent years, rational choice theorists have staked a claim for the comprehensiveness of their approach and have suggested that it may offer presidency scholarship the analytical and theoretical coherence it has lacked. Future research is likely to be driven in part by scholarly professional imperatives and, while rational choice and new institutionalism are at the cutting edge of presidency scholarship, that approach has not gone unchallenged. It remains to be seen whether the parsimony of rational choice theory can deal with the many and complex variables relevant to the study of the presidency.

Meaning

The term 'presidency' is applied to several distinct perspectives on the office of the President of the United States. Most commonly, and in its narrowest sense, it is employed as a label to refer to the incumbency of one particular President, as in the presidency of Abraham Lincoln or the presidency of Franklin Roosevelt. More broadly, the term applies to the historical development and legacy of a succession of presidencies since the office was established in 1789. In a more precise constitutional sense, the presidency is that branch of government established by Article II of the Constitution of the United States encompassing a set of constitutional and statutory powers and duties of the President together with additional 'implied' or 'inherent' powers and responsibilities not specifically enumerated in the Constitution or statute law. Finally, the term 'presidency' is used to denote the institutional structure of the office of President embracing the Executive Office of the President, a collection of staff units, originating from proposals contained in the Brownlow Report of 1937, that provide the President with the capacity to manage the work of the executive branch of government and to liaise with the principal constituents of the President, namely the Congress, the media and interest groups.

These different usages of the term present no significant analytical difficulties. In the literature on the U.S. presidency, the context is usually sufficient to clarify the sense in which the term is being employed and in none of its various forms is it conceptually or theoretically problematic. This is partly because the academic study of the presidency has not been as encumbered by rigid theoretical or conceptual frameworks as many other areas of the study of politics – a matter of concern to some presidency scholars who wish it were so, and a relief to others who see value in the broad, disparate, and eclectic approach that has characterized the study of the presidency to date.

Intellectual Context

The academic study of the U.S. presidency has mainly been the preserve of historians and political scientists. Historians have generally confined their attention to individual presidents and presidencies whereas political scientists have traditionally concentrated on the constitutional and political power of the presidency and its institutional structure and development over time. Few historians, with some notable exceptions (see, e.g., Schlesinger, 1973; McDonald, 1994), have focused on the broader institutional development of the American presidency and only a handful of political scientists (see, e.g., Milkis, 1993; Skowronek, 1993) have borrowed from the discipline of history to further what political science has had to say about the presidency. Given the vast amount of scholarship on U.S. presidents and the presidency produced by historians and political scientists, there has been little significant cross-fertilization between the two disciplines and it would not be unfair to say that the study of the U.S. presidency, as distinguished from the study of U.S. presidents, has been dominated by political scientists.

However, one should not ignore the contribution to literature on the presidency derived from the discipline of psychology, triggered principally by the publication of James David Barber's *Presidential Character* in 1972 (see, e.g., Simonton, 1987; George and George, 1998), nor, during the past decade, the participation of legal scholars in expanding the debate over the nature of executive power consequent upon the controversies generated by the presidency of George W. Bush (see, e.g., Yoo, 2005; Posner and Vermeule, 2010; Goldsmith, 2012; Fisher, 2013).

Until the publication in 1960 of Richard Neustadt's seminal work, *Presidential Power*, scholarship on the U.S. presidency had primarily focused on the constitutional and statutory powers of the President, the various roles and functions of the President, and its relationship to the other branches of government as exemplified in the classic texts of Edward S. Corwin (1957), Clinton Rossiter (1960), and Wilfred Binkley (1962). There has also been a strong normative tradition in the literature the presidency, but this has produced various and divergent diagnoses of the weaknesses of the presidency and no uniform prescription for change, although the British system of cabinet government or variants of it has tended to be among the more popular reform proposals.

Neustadt's *Presidential Power* brought the study of the presidency into contact with the behavioral revolution in postwar political science. Neustadt defined power in terms of the president's persuasive or bargaining ability derived from his 'professional reputation' and 'public prestige.' Asserting that 'powers are no guarantee of power,' he proceeded to show that the leadership ability of presidents was not inherent in the office but was highly personal and dependent on the President's own capabilities as a seeker and wielder of effective influence upon others involved in governing the country. Neustadt's immediate impact was to shift the concerns of presidency scholars away from the formal, legal, and institutional boundaries of presidential power toward a more behavioral and theoretical effort to locate the reality of power and leadership in the White House.

While Neustadt's work was a major break with the tradition of presidency scholarship it did not represent a departure from the basic values of the leading presidency scholars. Indeed, it reinforced those who were firm in their belief that the presidency was and ought to be the center of action in American politics and who advocated a strong and dominant presidency as the only institution capable of responding to the social and political problems facing the country. They represented a generation reared during the presidency of Franklin D. Roosevelt and who made FDR, or what was often referred to as 'the New Deal presidency,' the normative model for their scholarship.

The Changing Focus of Presidency Scholarship

Notwithstanding Neustadt's impact, the political science of the American presidency lagged behind the behavioral revolution for much of the 1960s and 1970s and not until the 1980s did the community of presidency scholars begin to exercise the kind of introspection and self-criticism on which behavioralism in America had thrived. That introspection produced a clear but belated appeal for the study of the presidency to connect with the basic tenets of the behavioral revolution – a more rigorous scientific methodology, the need for quantitative measures, and a greater concern for the conceptual and theoretical underpinnings of presidency scholarship (see, e.g., Edwards and Wayne, 1983). That appeal did result in a redirection of the focus of presidency scholars and, over the past 30 years or so, the political science of the U.S. presidency has taken a quantum leap theoretically, methodologically, and conceptually. A leading contemporary scholar of the presidency, Terry Moe, has described this development as a 'revolution' and 'fundamentally a revolution in theory' (Moe, 2009).

The fundamental values of presidency scholars also changed around the same time. The combined effect of the Vietnam War, Watergate, and the response to 9/11 led to a significant reassessment of the New Deal model of presidential power and even those who continued to advocate strong presidential leadership became more sensitive to notions of accountability and restraint. By the end of the century, presidency scholarship had begun an assault on what Mark Peterson called the 'presidency-centered perspective' on American government (see Peterson, 1990; Jones, 1994; Fisher, 2012).

Current Theory and Research

The epistemological transformation of presidency scholarship from the mid-1980s could not properly be called a revolution because it did not succeed in displacing older, established approaches entirely. The 'public law' tradition, for example, has flourished during the past two decades, in part due to the highly regarded contributions of Louis Fisher (see, particularly, Fisher, 2013) and triggered by the practical relevance of issues such as the war power, the legislative veto, impoundments, military tribunals, and impeachment. Scholars following in the footsteps of Corwin have made significant contributions to the study of the presidency that have not been dependent on theoretical sophistication or quantitative methodology. Similarly, the 'institutional' school has also been reinvigorated by political developments in recent times. Watergate and the Iran-contra affair, for example, acted as a catalyst for substantial research on the role of the presidential staff and the structure and organization of the Executive Office of the President (see Burke, 1992; Hart, 1995; Walcott and Hult, 1995) and, although much of this work is theoretically and conceptually grounded, it also builds on the descriptive and empirical approach that underlies the 'institutional' tradition in presidency scholarship.

The breadth of current research on the U.S. presidency would be difficult to categorize. In addition to those areas mentioned above, it encompasses the study of presidential personality and leadership style, decision-making processes, popularity, professional reputation, bargaining and persuasion, personnel management and the bureaucracy, media management, presidential rhetoric, the impact of public opinion on presidents, the impact of presidents on public policy, and much more. The current scope of the study of the U.S. presidency is well illustrated in the almost-800 pages of *The Oxford Handbook of the American Presidency* (Edwards and Howell, 2009).

Current research also embraces a variety of approaches and techniques which, when combined with the range of subject matter, makes presidency scholarship a broad, diverse, and pluralistic area of study open to the criticism that it lacks coherence in focus and methodology. But it would also be true to say that much current research on the presidency builds upon and extends the seminal research of the past and, while there may not be a single, coherent approach to the political science of the American presidency, there is continuity of research concerns coexisting with a willingness to utilize new methodological and theoretical developments.

Rational choice theorists, however, have staked a claim for the comprehensiveness of their approach and suggested that it may offer presidency scholarship the analytical and theoretical coherence it presently lacks (see Moe, 2009). Applications of rational choice theory to the study of the presidency are growing in number and recent work by rational choice theorists, particularly in the field of presidential–congressional relations, has made a significant impact (see especially Krehbiel, 1998; Cameron, 2000; Beckmann, 2010) and laid the foundations for an extension of that approach to other hitherto less theoretically receptive aspects of the presidency, such as presidential–bureaucratic relations (see Lewis, 2008).

Methodological and Theoretical Problems

Although the cutting edge of presidency research is in the hands of the rational choice theorists and their close companions the new institutionalists, their approach has been contested by other presidency scholars who are less convinced of its general utility across the spectrum of presidency scholarship and who question the desirability of imposing a conceptual and methodological uniformity on future research. The debate is exacerbated by the tendency of the new institutionalists to distinguish between the 'institutional' and the 'personal' presidency, rejecting the latter in the interests of parsimony and theoretical clarity. While it is true that behavioral studies of the 'personal' aspects of the presidency, as exemplified by James David Barber's pioneering work on presidential personality (Barber, 1972), revealed how difficult it is to theorize on the basis of a large number of complex variables, that has yet to be accepted as a sufficient argument for ignoring the complexity of the U.S. presidency.

A more longstanding methodological problem for presidency scholars is the lack of access to their subject of study. Presidents of the United States generally do not give interviews to political scientists, nor do they respond to questionnaires, nor for the most part can they be observed at work, neither do their memoirs or papers usually provide the kind of data that presidency scholars require. This is a principal reason why the study of the presidency has lagged behind other branches of the U.S. government in terms of scientific rigor and why the gaps in the state of knowledge about the presidency are still quite substantial.

Future Directions

During the past 30 years, research on the presidency has been driven in large measure by two principal forces – the behavior of presidents themselves and the events associated with their presidencies, and the imperatives of the political science profession. In all probability, these two forces will likely determine the direction of presidency research in the foreseeable future.

Presidency scholars have often been caught unprepared by the behavior of recent presidents and the events surrounding their presidencies. The Vietnam War was a catalyst for substantial research on the war power. The growth and expansion of the presidential staff system was barely studied before Watergate. The weakness of Jimmy Carter as President provided the impetus for Polsby's (1983) landmark study of the reformed presidential nomination process and its impact on the nature of the presidency. Ronald Reagan's public popularity prompted numerous studies of 'going public' strategies of presidential leadership (see especially Kernell, 1986). As long as occupants of the White House continue to surprise scholars of the presidency they are likely to influence the range and nature of future research.

Similarly, the professional emphasis on theoretical sophistication and scientific rigor is likely to determine the priorities of future research on the presidency as it has done in the past. The danger is that such imperatives may overwhelm and marginalize those aspects of presidency scholarship where theory and quantitative methods are less applicable and less suitable to the object of study.

Abstract

This article analyzes presidentialism and semipresidentialism in the context of a comparative study of forms of democratic government. It highlights the consequences of a dual democratic legitimacy of presidents and congress, and enumerates the possible patterns of conflict and/or compromise. The election of presidents and congress for fixed time periods and their mutual independence generates a distinctive rigidity compared to parliamentary regimes. The essay summarizes the negative consequences, basically derived from the above-mentioned defining characteristics, particularly divided government. It also presents the arguments in favor of presidentialism. A number of less essential or variable characteristics are noted, like different forms of election and the implications for the party system and public policy, as well as for the relation to the bureaucracy and the military. A reference is made to the debate about the instability of presidential democracies. In a second section semipresidentialism is defined. The proliferation of such systems in recent times, in many cases dubiously democratic, and the need to distinguish the 'formal' and the 'material' constitution is noted. Formally semipresidential regimes actually function as parliamentary. Particular attention is given to the case of the Fifth French Republic, as the pragmatic case and to the pattern of 'cohabitation' when the president is elected by one party (or coalition) and the prime minister depends on the confidence of a parliament with a majority of a different party or parties. The success in France should not hide situations in which no prime minister enjoys parliamentary support, like at the end of the Weimar Republic in Germany where the president appointed cabinets that could not find support in the Reichstag, a pattern that led to the appointment of Hitler as chancellor.

Democratic governance takes two basic forms: parliamentarism and presidentialism; some people would add semipresidentialism, leaving aside the very unique Swiss institutional structure. Each of them presents a variety of forms that lead to question the dichotomy. There are a few defining characteristics from which many consequences can be derived. Each is identified with a paradigmatic case: the British Westminster parliamentarism, US presidentialism and the semipresidentialism of France. However, as Sartori (1994) notes, parliamentarism takes a variety of forms like the German Federal Republic – the Kanzler democracy – and the assembly parliamentarism of the Third and Fourth French Republics, and contemporary Italy.

Presidential systems are based on an executive with considerable powers in the constitution, and generally with full control of the composition of the cabinet and the administration, elected by the people (directly or by an electoral college elected for that purpose) for a fixed period of time, and are not dependent on a formal vote of confidence by the democratically elected representatives in a parliament. The president is not only the holder of executive power, but is also the symbolic head of state who cannot be dismissed between elections except in rare cases of impeachment.

Two features stand out in presidential systems:

a. Both the president, who controls the executive and is elected by the people (or an electoral college elected by the people for that sole purpose), and an elected legislature (unicameral or bicameral) enjoy democratic legitimacy. It is a system of 'dual democratic legitimacy.'
b. Both the president and congress are elected for a fixed term, the president's tenure in office is independent of the legislature, and the survival of the legislature is independent of the president. This leads to what we characterize as the 'rigidity' of the presidential system.

Most of the characteristics and problems of presidential systems flow from these two essential features. Some other nondefining features of presidentialism are often associated with it, such as term limits or no re-election, automatic succession by a vice-president, more or less extensive rule making, and emergency powers. One characteristic, so normal that it can be included in the definition, is that the presidency is a unipersonal office. There have only been two cases of directly elected pluripersonal 'presidencies': the two-person Cypriot administration (1960–63) and the Uruguayan Colegiado (which governed twice – 1918–33 and 1952–67).

The basic characteristic of the president is the full claim to democratic legitimacy. The claim very often has strong plebiscitary components, although sometimes it is based on fewer popular votes than are received by many prime ministers in parliamentary systems heading minority Cabinets. The presidency gives the incumbent, who combines the qualities of head of state representing the nation and the powers of the executive, a very different aura and self-image, and creates very different popular expectations than those redounding to a prime minister with whatever popularity he might enjoy after his party receiving the same number of votes.

The most striking fact is that in a presidential system, the legislators, particularly when they represent well-organized, disciplined parties that constitute real, ideological, and political choices for the voters, also enjoy a democratic legitimacy, and it is possible that the majority of a legislature might represent a different political choice from that of the voters supporting a president. Who, on the basis of democratic principles, is better legitimated to speak the name of the people: the

president, or the congressional majority that opposes his policies? Since both derive their powers from the vote of the people, a conflict is always latent and sometimes erupts dramatically; there is no democratic principle to resolve it, and the mechanisms that might exist in the constitution are generally complex, highly technical, legalistic, and therefore of doubtful democratic legitimacy for the electorate. It is no accident that in some of those situations the military intervenes as 'poder moderador.'

It could be argued that such conflicts are normal in the USA and have not led to serious crisis. It would exceed the limits of this essay to explain the uniqueness of American political institutions and practices that have limited the impact of such conflicts, including the unique characteristics of the American political parties that lead many American political scientists to ask for a more responsible, disciplined ideological party system.

In a unipersonal presidency there is only one winner who gains full control of the executive. It has been argued that in a Westminster parliamentary system a party winning an absolute majority is also (or even more) a 'winner take all' while in a presidential system it is less likely that a president will have an absolute majority in congress for the entire period of his mandate. However, it is a president, one person that wins control of the executive rather than a party, and that person gains that power irrespective of the size of his plurality or in a runoff in a narrowed competition in which necessarily one candidate will have a majority. The loser in a presidential election ends with no public office in contrast to the leader of a defeated party in a parliamentary election likely to hold a seat in Parliament. Part of the unipersonal election is, in many presidential systems, the succession by a vice-president chosen by the nominee using criteria that would not have been those of the electorate or a party leadership.

The plurality rule remains the most common method for electing presidents. However, the fear of a president being elected by a small plurality has led to introduce a majority runoff election among the two leading candidates (when no candidate has received a majority). The plurality rule (Shugart and Carey, 1992) favors a two-party competition or at least the formation of broad pre-election coalitions and discourages candidates from minor parties. The runoff election, on the other hand, encourages a larger number of candidates in the first run, either in the hope to make it to the runoff (even with a modest number of votes) or place themselves in the condition to bargain for their support by one or the other of the two front runners.

Each procedure can have negative consequences. The plurality rule in a fragmented party system can lead to the election with the support of a small minority. The runoff in addition to encouraging party fragmentation in the first run, can create false coalitions (which will not hold after the election), or mortgages the candidate with allies which may exact a price or distort his image. It also generates in the winner the feeling that he represents the majority of the people, though in the first run he had weak support and his opponent might have been ahead.

In a multiethnic society the fear that a candidate from a populous state could be elected against those from other ethnic-religious communities, has led to a complex system of concurrent pluralities, to assure the election of a president with appeal across ethnic groups (as in Nigeria).

There are a few instances in which the popular vote, in the absence of a decisive majority, does not determine the winner. In Chile, before 1973, the Congress chose the president in the event that no candidate received a majority of popular votes among the top two contenders. Traditionally the one with the largest plurality was elected. In the USA, when in the non-deliberative electoral college no candidate obtains the vote of the majority of electors at the first count, the decision goes to the House of Representatives.

The fixed term of office of both presidents and congress introduces a particular rigidity. A failed president cannot be (normally) forced to relinquish power, but is obliged to continue governing, and he cannot (constitutionally) dismiss a congress committed to oppose his policies. A failed parliamentary prime minister can lose a vote of confidence, be replaced by another leader of his party or coalition, and if he feels that the opposition is wrong, call for an election hoping to discipline his party or coalition and/or revalidate his authority. The rigidity and the length of some presidential mandates leads to the frequent rule of no-reelection, or of no continuous reelections.

The dual legitimacy resulting from separate election of president and the legislature and their mutual independence can lead to 'divided government.' The congress and the presidency may be controlled by different parties (or factions of the same party) creating an impasse. How to govern?

Ackerman (2000) has developed three scenarios. The first emphasizes accommodation, based on bargaining, they may be called the Madisonian hope. Fiorina (1996) argues that American voters desire a divided government because they are uncertain about endorsing an ideological direction offered by either party. Mayhew (1991) argues that divided government has not impeded major legislation. The second involves constitutional breakdown, in which one or another power assaults the system and installs itself as a single lawmaker. A situation of this type is in Latin America, where traditionally the military as 'poder moderador' intervened temporarily, or more recently assuming complete power. Referring to my analysis (Linz, 1994), Ackerman calls this breakdown the 'Linzian nightmare.' A third less dramatic alternative is backbiting, mutual recrimination, and partisan deadlock, which he calls 'crisis of governability.' To the use of constitutional or extraconstitutional decree powers, emergency legislation, patterns described in detail by Carey and Shugart (1998) and their collaborators in a chapter significantly entitled 'Calling Out the Tanks or Filling Out the Forms,' I would add a fourth alternative that explains the absence of recorded conflicts: the application of the 'rule of anticipated reactions.' The avoidance of conflict by not initiating policies is likely to lead to conflict even when desirable, necessary, and proposed by the president at the time of his election.

The disjunction between the image of the voters and the president himself as an initiator of major policies, reforms, and change, and the gridlock, mutual blaming, and/or of a frustrated president or congress confronted with *decretazos*, an avalanche of decrees as *faits accomplis*, reducing the legislature to impotence, does not contribute to political

efficacy and the legitimacy of either or both institutions. The breakdown of democracy and the turn to unconstitutional rule or authoritarianism is only one possible outcome. 'Formal' democratic continuity, particularly in recent crises in Latin America (or the ex-USSR countries) is no proof that the system works.

The situation that Ackerman calls of full authority, when the presidency, the House and Senate are controlled by the same party and there is a favorable majority in the Supreme Court is rare and may last a short time. The result is a burst of legislation, law-making initiatives that will be strong in symbolic statement and difficult to change afterwards, with less concern about implementation. In a parliamentary system, where laws can more easily be changed with electoral defeat, governments are more interested in statutes framed in mid-sized concepts keyed to operational realities, to make them work.

Although the separation of executive and the legislative power, more accurately separate institutions sharing powers, implies that the bureaucracy (and the military) are the domain of the presidency, the fact is that they have two masters. Congress is perhaps increasingly adept to intervene in details of public administration and defense thanks to the prerogative of 'oversight,' of financing departments and programs, the long-standing freedom to investigate. A result is the dependence on both the presidency and the congress and indirectly the separation from both, and subordination to neither. A response to this situation has been 'politicized professionalism': the growing number of political appointees, the large number of in-and-outers, and the short tenure of those appointed who prefer to move to the private sector (and consequently the lack of accumulated experience and continuity in policies). The president turns to 'loyalists' rather than experienced civil servants who would be concerned about their relations with powerful congressmen or women.

In the ongoing debate over the success or failure of presidentialism it is important to distinguish:

a. The basic theoretical issues derived from the defining characteristics of presidentialism (Linz, 1994; Shugart and Carey, 1992).
b. The problems for presidentialism not derived from the basic characteristics; like no reelection, tensions with vice-presidents, mid-term congressional elections, etc.
c. The problems with presidentialism and the actual breakdowns of presidential compared to parliamentary systems. A comparison plagued by a number of methodological problems; time period covered, regional comparisons, level of economic development (OECD vs developing countries), and increasingly formal stability with 'defective' democracies (some actually authoritarian regimes) (Stepan and Skach, 1994; Shugart and Carey, 1992; Thibaut, 1996).
d. The absence of a possibility of a transition to parliamentarism and therefore the limited relevance of a theoretical comparison and the need to consider 'improvements,' modifications of presidentialism that correct some features contributing to some of its failures.
e. The need to keep the problems of semi-presidentialism, offered as a more viable alternative to presidentialism, separate. In this case, the lack of consensus on which countries are semipresidential and the small number of cases (at least before the new postcommunist regimes), makes an analysis like (c) difficult.

The basic argument for the separation of powers is that it provides mutual checks, enhancing freedom, preventing the concentration of power enjoyed by a British prime minister. Mutual checks, the greater difficulty in enacting policies, the opportunity for all interests to be heard and taken into account, the slowing down of the process, and the opportunity for vetoes, generate weak executives and block many of their initiatives, and this is presumably what the voters want when they split their vote for congress and the president. Perhaps this is an advantage in a society that works well independently of public policies, in a wealthy market economy with no major need for redistributive policies, or with independent nonpolitical agencies, but is unlikely to fit societies facing serious problems of underdevelopment and social injustice, requiring more effective government action.

Among the positive aspects of presidentialism its advocates list:

The separation of powers of congress and the executive allows the 'representatives' to act as representatives of interests, particularly of those with a geographical basis, since they are not bound to support the policies of the executive and no party discipline is needed to support a government. In the absence of proportional representation, they enjoy considerable independence from the party leadership and are more likely to represent interests rather than broad policy or ideological alternatives. All politics become local. As Sartori (1994, p. 84) writes: three factors "ideological unprincipledness, weak and undisciplined parties, and locality centered politics, contribute to the working of US presidentialism."

The separate election, particularly mid-term elections, and the limited influence of the president in many cases in the nomination or the making of lists of candidates (especially in federal systems) and in their electoral success, makes the representatives independent. Even their own partisans will owe them almost nothing and often doubt their usefulness in the elections. The selection by primaries has probably reinforced that tendency. This makes members of congress, compared to parliamentarians, better representatives of interests of their constitutents but less reliable in supporting a party (and presidential) policy program. In fact, that 'representative' function is seen (Shugart and Carey, 1992) as one of the positive aspects of presidentialism.

One presumed advantage is the identifiability of presidents, compared to the incertitude of who will head the government in some parliamentary systems based on coalition-making among multiple parties after the election. However, in many parliamentary systems the voter knows well who will head the government if the party he votes for wins. Although presidential candidates identify themselves with certain policy goals, they are less bound to a program than a party and the prime minister it supports, or minor parties that make their coalition support dependent on certain demands (for example, national minority parties).

Shugart and Carey (1992, pp. 44–45) consider the personal identifiability the basis for greater accountability. This might be true, except when reelection is barred and for the blaming game

between the president and congress (particularly in the case of divided government).

Presidential elections allow the citizen to choose one individual to put his trust in – on account of real or perceived qualities and commitments without the mediation of complex institutions: a party, a legislature, or a plurality of actors like parties forming a coalition. That personalization simplifies the choice. It also permits outsiders, not identified with a party, who may not have held any office before, to appeal personally and directly to the voter: Collor, Fujimori, Tyminski, Perrot. That appeal requires access to the media, which in turn may involve access to funding – in some cases personal wealth – and considerable misunderstanding of what is necessary to govern. It may also appeal to 'being above parties,' perceived as divisive, somewhat like a monarch. The election of military leaders: Mannerheim, Hindenburg, De Gaulle, Eanes, even Eisenhower, reflects this desire. TV is particularly congruent with these patterns.

Latin American presidents greatly vary in terms of their constitutional powers, both reactive (veto power, for example) and proactive (decree legislation) and in terms of their partisan support in congress. The possible combinations (Mainwaring and Shugart, 1997, pp. 40–54) are too complex to summarize here.

The difficulties with presidentialism in Latin America have generated two opposite responses: attempts to curtail the powers of the president out of fear of the abuse of power and authoritarian predispositions and efforts to strengthen the presidency as an answer to the weakness of the presidency, particularly in relation to congress.

Many presidential systems have a vice-president, with limited functions except when he has to step in to succeed the president for reasons of death, resignation, impeachment, or incapacity. He generally is not elected independently but on a ticket with the presidential candidate, chosen by him, often for electoral or personal reasons without concern about his or her qualifications. The frequent destructive conflicts between presidents and vice-presidents have led to recent constitutions to not include that office.

Semipresidentialism

Semipresidentialism as a distinctive form of organizing democratic political life, gained importance as a constitutional model and political reality with the consolidation of the French Fifth Republic defined by Sartori (1994, p. 132):

a. The head of state (President) is elected by popular vote – either directly or indirectly – for a fixed term of office.
b. The head of state shares the executive power with a Prime Minister, thus entering a dual authority structure whose three defining criteria are (c) to (e).
c. The President is independent from parliament, but is not entitled to govern alone or directly and therefore his will must be conveyed and processed via his government.
d. Conversely, the Prime Minister and his Cabinet are president-independent in that they are parliament-dependent: they are subject to either parliamentary confidence or no-confidence (or both), and in either case need the support of a parliamentary majority.
e. The dual authority structure of semi-presidentialism allows for different balances and also for shifting prevalences of power within the executive, under the strict condition that the 'autonomy potential' of each component unit of the executive does subsist.

Shugart and Carey (1992) prefer to call this system 'premier presidentialism' and distinguish it from 'presidential parliamentary' (which others include under semipresidentialism) on the basis of the constitutional position of the president.

Since its inception in the constitution of the Weimar Republic (1918) and the Finnish Constitution, it has been the object of considerable dispute. Different terms were used to characterize it: bipolar executive, parliamentary presidential, and Duverger established the term semipresidentialism. The ambiguities surrounding it lead some authors to treat it as a variant of presidentialism, while others see it as a form of parliamentarism. This author, as Sartori, considers it a form *sui generis* distinct from both presidentialism and parliamentarism.

Bartolini (1984) has shown that semipresidentialism was introduced in countries that achieved independence and sought a symbol for the new nation (Ireland, Iceland, and earlier in Finland). In Portugal, it was an attempt to overcome the uncertainties of a transition to democracy.

The French semipresidentialism of the Fifth Republic after the introduction in 1962 of direct presidential election is a two-headed system. It makes possible the alternation – according to some authors – between presidential and parliamentary phases depending on the party or parties of the president having a majority in the chamber. Sartori, rightly, prefers to speak of 'oscillation,' since, in the case of split majorities – described by the French as 'cohabitation' – the president retains some specific powers, particularly in foreign affairs and is not reduced to the status of a president head of state in a parliamentary republic. Nor can a president cum government, that has to govern with and through another body, be assimilated to a 'pure' president that governs alone, that is the government. The oscillation assures considerable flexibility and until now 'cohabitation' has worked relatively well.

Elgin (1999, p. 14) lists countries that he considers semi-presidential: 6 in Western Europe: France, Finland, Portugal, Austria, Iceland, and Ireland; 5 in Central and Eastern Europe: Poland, Bulgaria, Romania, Croatia, Macedonia, and Slovenia; 11 in the former USSR: Russia, Ukraine, Lithuania, Moldavia, and Belarus (of them in the Asian belt: Armenia, Azerbaijan, Kazakstan, Kyrgyzstan, and Uzbekistan; 5 in Asia and the Middle East: Lebanon, Maldives, Mongolia, South Korea, and Sri Lanka; 3 in America: Dominican Republic, Guyana, and Haiti; and 11 in Africa. A total of 42 countries, among which only 18 in 1999 were rated from 1 to 3 on the Freedom House index of political rights; 6 in Western Europe, 4 in Central and Eastern Europe, 1 (Lithuania) in the ex-USSR; 2 in Asia; 1 in the Americas; and 4 in Africa.

The conclusion about regimes that from a formal constitutional perspective and definition can be classified as semi-presidential is that the material constitution (the actual working over time) varies enormously. In some, the president, although popularly elected and with considerable legal powers, acts more like a president in parliamentary regimes. One

difficulty is that a large number of countries that have adopted semipresidential institutions are new democracies, and are politically unsettled (and doubtful democracies), and it is premature to characterize those polities. Moreover, much depends on the personality and political goals of the founding presidents and their successors.

Though all conceptual classification of forms of government cover a wide range of variations, this is even truer about semipresidential given the ambiguities in the constitutions about the powers of presidents and prime ministers, the role of leadership and personality, and the fact that the extended list of such regimes includes many countries dubiously democratic.

On the basis of the long-time actual working of formally semipresidential regimes, Linz (1994) has excluded Austria, Ireland, and Iceland from the list and he and Sartori (1997) would also exclude Portugal after 1982.

The dual legitimacy resulting from the separate direct election of president and parliament persists in semipresidential regimes, but the principle that a prime minister requires the confidence of a majority in the parliament reduces – perhaps even eliminates – the conflicts derived from 'divided government.' The French constitutional practice in the situations of 'cohabitation' supports that interpretation, though one might still ask to what extent it reflects a long tradition of parliamentarism (in addition to other favorable conditions).

We might add to the complexity (and perhaps confusion) a distinction between formally semipresidential regimes in which the president exercises significant powers (and is expected to do so) and those where he has not done so (and is not expected to do so). We obviate the argument that the formal institutional structure is not irrelevant, and that in fact it might at some point become politically relevant. The formally but not materially semipresidential regimes on that account are not parliamentary though they may work as parliamentary. More complicated is the issue – not considered in the earlier studies of this regime type – of the president enjoying such formal and actual powers that the prime minister and his cabinet are fully dependent on the president and the parliament, though formally empowered to question that dominance, is unable to do so. Should such regimes be considered presidential rather than semipresidential? The question can be raised about Russia and Sri Lanka. Again, the complex constitutional rules cannot be ignored but so can the actual working of the system under Yeltsin not be fitted into a 'semipresidential mode.' With such a narrowing down we still would have a number of working stable pure semipresidential regimes.

Presidents generally are identified with a political party, a leader of a party, or after winning the nomination of a party become its leader (yet when defeated lose that position). However, in Russia, Yeltsin, though elected with the support of the parties, opted for not identifying with a party and the constitution formally forbids the president from being a party member. The same is true for other post-communist presidential or semipresidential constitutions.

The idea of president above party, not identified with a party and not campaigning for a party, is likely to make it more difficult for a president to have party support, and does not contribute to the building of strong parties.

Semipresidentialism can work well when the presidential majority and the majority in parliament are of the same party or coalition and when, without being the same, there is a majority in the chamber, supporting a prime minister of a different party (the French 'cohabitation'). The system becomes more problematic as Kalteefleiter (1970) has analyzed in detail when the parliament is unwilling or unable to provide support to the choice of prime minister or of the president but is also unable to support someone of its own choice. This can be the case of a highly fractioned parliament or of a polarized pluralism in which the extremes make it impossible for the center to govern. Parties might be ready to tolerate weak presidential cabinets (abdicating their responsibility) and the president governing by decree. The president, on the other hand, having the power of dissolution, may be tempted to call for elections to solve the impasse and construct a majority. Repeated elections in a climate of crisis might deepen the crisis and contribute to strengthen the antisystem disloyal or semiloyal oppositions. These patterns developed in Germany under the presidency of Hindenburg and his presidential cabinets, contributed to the breakdown of the Weimar Republic.

Editor's Note

Juan Jose Linz was emeritus professor of political science at Yale University and an acknowledged expert on theories of totalitarian and authoritarian systems of government. In addition to his many contributions to political science, he also was a significant figure in post-War political sociology. Linz died October 1, 2013. His aritcle on Presidential Government is being reprinted as a "Legacy entry."

Pretend Play and Cognitive Development

Abstract

When children pretend, their behavior is driven by their imagination and capacity for seeing the world in a way that is contrary to how really it is. They use objects in ways that are inconsistent with their intended purpose, attribute items with properties they do not have, and act as someone they are not. Doing so is a unique human universal that is associated with a range of core social cognitive achievements. Here, evidence is outlined for the cultural universality of pretense alongside explication of the links between pretending and other developmental domains.

> … a man does not learn through any kind of instruction or study in later life anything like so much as the child learns in the first four years of his careless existence, through the perceptions and ideas acquired in his play.
> – Preyer (1893)

Every family of mammals shows some evidence of play in some species (Burghardt, 2005). In humans, play emerges early in ontogeny, and in its initial expression, it is characterized by the functional treatment of objects where infants attend to cause-and-effect relations with objects, focusing on literal and intended uses, such as pushing a toy on wheels or placing building blocks together. Toward the end of the second year, infants begin to demonstrate an interest in applying their knowledge base to symbolically manipulate objects and their properties, and to allow their imagination, rather than the stimulus itself, to dominate their behavior: They begin to pretend (Harris, 2000; Leslie, 1987).

When children pretend, their play becomes characterized by the symbolic, nonliteral transformation of the here-and-now whereby the world, in the context of a play sequence, gets treated contrary to reality. A banana is talked into as if it is a telephone. An empty cup gets 'sipped' from as if it contains hot tea. A red block becomes a poisonous fish (see **Figure 1**). With development, children's pretense incorporates ever more complex and cognitively demanding routines, as simple behaviors directed toward the self translate to more sophisticated actions involving sequences and object substitution. During this time, the meanings that are associated with pretend play become augmented by a differentiation from real-life conditions and situations, persons, and objects that are immediately present.

Many developmental psychologists are motivated to search for the ontogenetic origins of behaviors that define the human condition. The less culturally specific a behavior is and the more it has demonstrable, replicable links to other core domains of development, the more likely it is to be considered in this light. Pretend play is rare in that it satisfies both criteria. In the following sections, I first outline evidence for the cultural universality of pretend play and then follow by detailing aspects of young children's social and cognitive development that are intimately tied to their engagement in and expression of pretense.

Pretend Play in a Cross-Cultural Context

As a discipline, psychology has been criticized for making claims about human behavior that are staked in ignorance of the vast majority of the world's population (Arnett, 2008; Henrich et al., 2010). To some degree, this is true of the pretend-play literature, where cross-cultural studies remain a minority. There is, however, a sufficiently broad base from which valid generalizations can be made. Foremost among these is that engaging in pretense can be genuinely considered a human universal. Children of !Ko and !Kung hunter-gatherers in Southern Africa will pretend to be animals and the adults who hunt them; melons will be used to make dolls that are treated as babies (Sbrzesny, 1976, as cited in Konner, 2010). Among the agricultural Kpelle of Liberia, children act out roles they see adults engaged in, such as being a blacksmith (Lancy, 1996). Martini (1994) reported that children living in the French Polynesian Marquesas Islands

Figure 1 Typical pretend act of young Western children. In this sequence, a 3-year-old boy (left) explains to his 6-year-old brother that the red plastic blocks are 'poisonous fish.'

pretended to paddle canoes, hunt, and fish, while Roopnarine et al. (1994) noted that children in India will act out traditional celebrations and folktales. Indeed, wherever evidence of pretense has been sought, it has been found. There are differences in what children do and in the frequency and duration with which they do it, but what is beyond question is that no matter the environment in which they grow, children spend a considerable portion of their early years pretending.

Pretend Play in Five Distinct Brazilian Communities

Providing clear examples of cross-cultural similarities and differences, Gosso et al. (2007) indexed the naturalistic free play of 4–6 year olds living in five distinct cultural communities in Brazil: Parakanã Indians (from Paranowaona in the Amazon region in the north), seashore children (from Ubatuba, a small town of the southeast), and urban groups of low, mixed, and high socioeconomic status (SES) from São Paulo, a metropolis of the southeast.

Critically, in terms of the proportion of time spent playing, pretense was among the highest of all play types for children in all cultural groups. Children in all groups also engaged in more acts of symbolic modification (this included acts in which the self or another was attributed an identity different from reality, using an object to stand in for another, attributing properties to objects that the children do not have, and pretending to be in a noncurrent physical state, e.g., being sick) than symbolic creation (imagining something is present when it is not, e.g., pretending to be in a spaceship or taking a shower with soap in the absence of any substratum). Finally, when engaged in socio-dramatic play, all children mainly assumed *the identity of family members* (e.g., a 5-year-old seashore girl pretended to be the mother of another girl, ordering her to buy milk, candy, chocolate, and cake at the grocery store). The second girl then went to a bench, pretended it was the grocery store, and returned showing an imaginary bag, asking, ("Was it just that that I was supposed to buy?"), followed by *animals* (e.g., a 5-year-old Indian girl said she was a turtle, 'jumping' into the 'river' and 'swimming') and *fantastic characters* (e.g., a 5-year-old mixed-SES urban boy put an orange cloth on his shoulders and invited a 4-year-old peer to play vampire, saying, "I have been wearing this cloth for more than a thousand years. I could borrow it to you").

Along with these similarities, clear differences were found. For example, the high-SES children showed a greater proportion of symbolic modifications than seashore, Indian, and low-SES children, with the mixed-SES group showing a higher frequency than Indians. The high-SES urban children also engaged in more 'creation' than low-SES children and Indians, with the mixed-SES children falling in between. Among Indians, object property modification (e.g., using a toy wooden boat for a real boat) was more frequent in boys, whereas object identity (e.g., using a lemon in place of soap or a leaf for a washbasin) predominated in girls. A similar pattern was observed among seashore and mixed-SES urban children, but character identity modification (e.g., pretending to be a mother, child, horse, or dog) was more common in this group than object identity modification. Gosso et al. (2007) also found that transportation themes featured prominently among Indian children. Interestingly, although they are common and readily available for all members of the community to use, canoes were rarely included during pretend-acts by these children. In contrast, they often pretended to drive, pickup trucks and motorboats, both of which are status symbols being needed to make long-distance travels. Similarly, driving a car was a common theme for children living in the low-SES urban community, where having a car is an indication of heightening of social class.

Pretend Play in Three Geographically Distinct Communities

In a more recent study, 1–3-year-old children's expression of and engagement in pretend play were investigated in three distinct communities: in two traditional, small-scale cultural settings in rural Peru and rural India, and in a typical Western, middle-class cultural setting in Canada (Callaghan et al., 2011). As in Gosso et al. (2007), similarities and differences were found. Asked when their children began to engage in pretense, most mothers suggested at around 2–3 years of age, regardless of their cultural heritage. Mothers also reported that when their children started to pretend, social role-play was the most common form. However, whereas the Canadian and Peruvian mothers said their children often pretended with others and would commonly use one object to stand in for another, Indian mothers said their children usually only pretend when on their own and rarely engage in object substitution.

To directly test for pretend abilities, Callaghan et al. (2011) gave children 2 min to play with a range of everyday items as well as sets of toys considered either conventional (e.g., a cloth doll with clothes, crockery and cutlery, and replica cars and animals) or nonconventional (e.g., a stuffed sock, cork coasters, shower mounting unit, and door stop). Once children had played with one set of toys, the experimenter demonstrated two symbolic actions with them (e.g., giving the doll a drink of juice and dancing the doll around the table, or smashing two cars together and having a close encounter with another car at an intersection) and encouraged them to play again. Children were then given the second set and encouraged once again to play the 'car' or 'doll' game with the new set of toys. Irrespective of background, children's rates of symbolic actions were higher for conventional than nonconventional toy types. However, in terms of overall rates of production, the Canadian children produced symbolic-acts with the nonconventional toys approximately five times more frequently and with the conventional toys about 2.5 times more frequently than children in India or Peru. With the nonconventional toys, over 40% of the Canadian children produced at least one symbolic act, whereas less than 10% of the children from the rural groups did so.

Callaghan et al. (2011) also investigated whether or not children would respond differently to an experimenter's attempts at either pouring from a container or eating a food item when these actions were couched as 'pretend' (where the experimenter adopted a pretense attitude while modeling the actions) or as 'trying' (where the experimenter demonstrated the same actions but conveyed effort rather than pretense).

For the trying trials, in terms of simple imitations of the experimenter's actions (e.g., trying to pour water from the closed container into the cup) and actions that went beyond those demonstrated (e.g., trying to open the lid of the container before pouring), children in all cultural settings performed at a high level. Notably, though, Peruvian children were moderately lower in their performance relative to Canadian and Indian children. However, in the pretend trials Canadian children performed considerably more actions, whether replications of what the experimenter modeled (e.g., pretending to bite the orange) or actions that went beyond those demonstrated (e.g., pretending to 'pour' into a container and then giving a 'drink' to a teddy bear) than Indian and Peruvian children. Moreover, the average age at which they produced at least one target pretend act was lower for the Canadian children (34.4 months) than the Indian (46.5 months) and Peruvian (45.8 months) children.

Summary

The aforementioned studies highlight how children's cultural background can have an important influence on their pretense, influencing factors such as how play is engaged in, who is played with, and what is used to play with. The differences in pretense outlined throughout this section are telling, but they are likely due to environmental factors. In explaining the lowered rates of pretense that they found in the Indian and Peruvian children, Callaghan et al. (2011) suggest that this is likely due to the almost absent input from supportive adults. They note that their interview data suggest that only the Canadian children engaged in frequent, rich, interactive pretend-play episodes with their mothers. In this context, cultural differences are attributed to differences in scaffolding, not competence or mental ability. Similarly, Gosso et al. (2007) argue that differences in the expression of pretense are environmentally bound and that "there are no differences in cognitive functioning of the children of various cultural backgrounds" (see also Göncü et al., 2000).

It has been argued that the emergence of childhood as a novel life stage is one of the most critical steps in the evolution of our species (Bogin, 1990; Locke and Bogin, 2006; Nielsen, 2012). Regardless of the veracity of this argument, what is clear is that irrespective of the environment in which they flourish, childhoods, the world over are, at least in part, spent pretending. To some, pretense may appear to be the pastime of a mind unencumbered by more serious, more vital pursuits. But its global pervasiveness suggests otherwise, something borne out by a large body of literature documenting links between the exhibition of pretense and a range of important social-cognitive behaviors.

Developmental Correlates of Pretend Play

In order to pretend, children must imagine something that is currently not true, then behave as if it were (e.g., by 'drinking hot tea' from an empty cup). When placed in the context of an extended scenario (e.g., having a 'tea party with friends'), the imagined world, along with the possible consequences of any behavior, has to be considered and maintained. If a cup is tipped over, whatever is 'spilled' should be 'cleaned up.' By pretending, children thus develop a capacity to generate and reason with novel suppositions and imaginary scenarios. The ability to pretend is thus afforded a special role in development, a role emphasized by associations between children's engagement in pretend play and the emergence and establishment of a host of other critical skills. This section outlines some of these.

Social Competence

In a large-scale study of the social and cognitive associations with young children's pretend play, Connolly and Doyle (1984) observed 91 children aged between 35 and 69 months engaged in free play at their child care centers. The occurrence and complexity of pretend-acts exhibited while interacting with others were correlated with (1) teacher ratings of children's competence in interacting with peers, (2) teacher ratings of how popular children were with other students, (3) children's ability to correctly identify how characters in a series of emotional stories might feel (e.g., a child's bag of candy is taken by another child), and (4) the amount of time spent in social interactions. Children's engagement in pretense did not correlate with a range of less socially oriented measures, such as (1) their competence in meeting the demands and regulations of the classroom, (2) their ability to select from an array of items those that would make appropriate gifts for different individuals (mother, father, teacher, and opposite-sex peer), and (3) the type of affective mood evident (rated as positive, negative, or neutral) while interacting with others. Whilst cautioning against interpreting causation from correlation, Connolly and Doyle suggest their findings which indicate that social pretend play is the most predictive of the skills and competencies that are apparent in children's social interactions with their peers, and that pretending provides a framework for the development of social skills (see also Taylor et al., 2004).

Research by Uren and Stagnitti (2009) explored pretend-play as a facilitator for social competence and involvement in school activities. Children were assessed with various measures to determine their engagement in pretend play, interactions with peers, and involvement in school activities. They reported that a higher complexity in pretend play (i.e., the ability to perform detailed and highly elaborate pretend interactions with conventional and nonstructured toys) was related to greater engagement with peers and better social abilities. Alternatively, children with poor pretend-play skills showed more disruptive behaviors in their interactions with peers. Children with complex pretend-play skills were also more involved in their classroom activities and showed greater cognitive abilities during play. These abilities included the introduction and extension of ideas and stories throughout play, and a higher level of verbalization.

These studies highlight the link between children's developing social skills and their engagement in pretend play. While the studies provide no foundation for assuming causality, intervention programs have exploited this link (e.g., O'Connor

and Stagnitti, 2011), using play as a successful means to improve young children's social skills.

Language

According to Piaget (Piaget, 1962), during the majority of the sensorimotor period, infants operate at a level of pre-representation, whereby behavior based on the evocation of an absent object (i.e., representation in thought) is not observed. However, at the end of the sensorimotor period (about $1^1/_2$ –2 years of age), the ability to represent something by means of a 'signifier' emerges. This provides infants with a medium for going beyond their current veridical perceptions and permits the appearance of a series of significant symbolic skills, including the ability to treat the real world in a nonliteral manner (i.e., pretend play). Werner and Kaplan (1963) saw the development of language in a similar light, conceiving language and play as outcomes of the general progress of the semiotic function.

In keeping with Piagetian theory, a number of studies have documented an association between pretend play and language development in childhood (e.g., Bates and Thal, 1991; Eisert and Lamorey, 1996; Lewis et al., 2000; McCune, 1995; Ungerer and Sigman, 1984). Some of these studies reported associations between pretend play and language comprehension prior to the middle of the second year (Lyytinen et al., 1997; Tamis-LeMonda and Bornstein, 1993, 1994). Hence, it may be that language comprehension scaffolds the pretense abilities of infants and young toddlers by providing them with a means of better understanding the overtures of others. Indeed, Kavanaugh et al. (1983) reported that, while playing with their infants aged between 12 and 21 months, carers almost exclusively initiated pretense episodes by verbally attributing properties to objects (see also Rakoczy et al., 2005; Striano et al., 2001).

This idea of attributing properties to objects relates to what is termed 'object substitution,' a core domain of pretense in which an object is treated in a manner other than its normal use (e.g., a banana is used as a telephone) or is designated as being something that it is not (e.g., a wooden block is labeled a 'fast car'). This type of pretense emerges in the second half of the second year of life and is initially constrained by the substituted objects being relatively simple in shape, having minimal surface details and being geometrically similar to the replaced object (Smith and Jones, 2011). A wooden block may be a 'fast car,' but a book cannot. To study whether this form of pretense is linked to language development through an emerging capacity to identify object properties, Smith and Jones (2011) tested children aged 18–30 months for productive vocabulary, object recognition (where they were asked to identify which of the three objects were named by an experimenter), and object substitution abilities (where children had to choose, from an array of four items, one that could be used in place of another – e.g., using a block of wood as a 'bed' for a doll). For the object tasks, children were tested using both rich and sparse (minimally representational) objects. Smith and Jones found a strong positive relation between children's sparse object recognition scores and the numbers of target object substitutions they produced, and that changes in visual object recognition were related to noun vocabulary size. For Smith and Jones, these associations indicate that while object substitutions are not causally related to language delay, their absence may be an easily detected signal of a problem in language acquisition.

Theory of Mind

The purported link between pretense and language was subject to increased empirical scrutiny following a proposal by Leslie (1987) in which he argued that children's ability to pretend was associated with the development and elaboration of the mental state lexicon and the subsequent emergence of a theory of mind. The term 'theory of mind' refers to a kind of 'commonsense understanding' of the world that involves the appreciation that oneself and others are beings who possess a range of mental states, such as thoughts, beliefs, and desires, and that it is these mental states that determine behavior. We act toward the world, not as it really is, but how we perceive or believe it to be. I may open my umbrella because I think it is about to rain. Whether it really is or is not about to rain is irrelevant – my behavior is driven by my belief that it will rain.

Tasks used to assess understanding of 'false beliefs' in others have become the standard tool used to index the child's developing 'theory of mind.' For example, a child might be shown a box that would typically contain a popular treat (e.g., an M&Ms box). When given the box to explore, the child discovers that it contains something unexpected (e.g., pencils). They are then asked what someone else who has never looked inside the box would expect to find. Children at around 3 years of age suggest that someone else would expect to find what they themselves know is inside the box (e.g., pencils), whereas by 5 years of age most children answer that someone else would reasonably expect to find contents reflecting what is depicted on the cover (e.g., M&Ms). Success on these tasks depends on the child's ability to distinguish between a mental representation (e.g., the belief of 'X' that the contents of a box reflect what is advertised on the packaging) and the actual state of the world (the box, unbeknown to 'X,' contains something unexpected).

Leslie (1987) maintained that to perform the nonliteral mental transformations that characterize pretense, children must first be able to simultaneously appreciate two alternative and contradictory models of reality such that the literal world is prevented from being corrupted by what occurs in the fantasy world. In a similar way, the idea of mental states cannot be discovered through either language learning (where conceptual understanding must necessarily precede linguistic expression) or perceptual evidence (given that mental states are unobservable). For Leslie, through the ability to appreciate the dual representations that are first evident in pretense, the pre-school child begins to relate expressions to the language of thought. Furthermore, it is this capacity for representational reasoning that the child subsequently exploits when constructing a theory of mind. The critical set of abilities contributing to the appreciation of belief and, hence, to the development of a mature theory of mind typically emerge between 3 and 4 years of age (Wellman meta-analysis). However, as noted in this article, children typically begin to engage in pretend acts from 18 months of age onward. In response to this apparent

asynchrony in development, Leslie (1987, 1988) has claimed that pretend play is in fact an early manifestation of the requisite abilities necessary for the development of a theory of mind.

In line with Leslie (1987), multiple studies have documented positive correlations between various indices of pretend play and children's success on false-belief tasks (for a summary, see Smith, 2010, p. 186, Table 9.1). For example, Taylor and Carlson (1997) assessed 3- and 4-year-old children's theory of mind development (as indexed by a series of 13 tasks, including false belief) and their involvement in pretend play. They found that variance in 4 year olds' performance on the theory of mind tasks was explained by both the creation of an imaginary character and a composite score derived from 20 fantasy play measures. Both results were maintained after the effects of chronological age and verbal intelligence were controlled for. However, of the fantasy measures, variance in theory of mind was best accounted for by three variables – the performance of imaginary-object pantomimes, the use of blocks as props in pretend play rather than as functional items, and the ability to impersonate another person. Furthermore, Taylor and Carlson comment that children who pretended to be a machine performed worse on theory of mind tasks than children who did not, thus proposing that gaining an appreciation of the causality of mental states obtained through impersonation occurs only in role-play involving animate beings.

Creativity

On 20 July 1969, in what must be counted as one of the crowning technological achievements of our species, Neil Armstrong and Buzz Aldrin stepped onto the surface of the moon. This occurred less than a century after the first manned heavier-than-air craft successfully took flight. During this same half century, the nearest that chimpanzees, our closest living animal relatives, got to flight was when they swung through the trees. While we invented tools to build spacecraft, their tool use has not radically changed from what was employed some 7 million years ago when we shared a common ancestor. But before we could fly to the moon, we needed the idea of rockets that could fly to the moon. We needed a mind capable of remarkable imagination and creativity – a mind that, for a number of theorists, develops through the pretense that occurs in children's play, where they get to practice the creative process that underpins innovation in adulthood (Carruthers, 2002, 2006; Pellegrini et al., 2007).

The idea that pretense and innovation are linked is not new (Almy, 1967; Bruner, 1972; Lieberman, 1977; Piaget, 1962; Sutton-Smith, 1967). Testing this purported link Dansky and Silverman (1973) gave a group of 4- to 6-year-old children 10 min to play with a set of objects that included paper towels, a screwdriver, empty matchboxes, and paper clips. An experimenter showed other children in another condition what could be done with these objects (e.g., turning screws with the screwdriver or putting small sticks into empty matchboxes). These children were subsequently asked to copy what the experimenter had done. Children in a third condition were given a box of crayons and four pictures to color in. Regardless of what condition they were in, each child was subsequently asked to suggest alternate uses for the four stimulus objects. Responses were scored according to whether they were standard (i.e., encompassing what the object had been primarily designed for, e.g., suggesting that the paper towel could be used to wipe up something) or nonstandard (i.e., suggestions that would not be typically associated with the object's design function, such as using a matchbox to 'make a TV' or using the screwdriver as 'a merry-go-round'). Children in the play condition produced significantly more nonstandard responses for each object, whereas there was no difference in the mean number of standard responses given (for replication, see Dansky, 1980; Dansky and Silverman, 1975; Li, 1978; for criticism, see Smith and Whitney, 1987).

In a study by Mullineaux and DiLalla (2009), the relationship between pretend play and later creativity was examined by comparing realistic role-play (e.g., pretending to be another person) at age 5 to divergent thinking at ages 10–15. This longitudinal design consisted of a free-play session for the initial measure of pretend-play role-playing, and two measures of creativity (i.e., divergent thinking tasks) at follow-up. The two creativity measures involved having the participant list various functions for eight objects and finish an incomplete drawing. It was reported that more realistic role-play at the initial observation was related to a greater ability to list alternative uses for items at follow-up. However, this relationship was not present for the drawing task.

Indirect support for pretense being the bedrock of creativity comes from the literature on children with autism who display impairments in both domains (Craig and Baron-Cohen, 1999; Jarrold, 2003). Evidence also comes from children who grow up in Old Order Mennonite communities, where a traditional rural existence is embraced and modern technology and innovations are shunned. In stark contrast to children raised in less conservative religious environments, the pretense of these children predominantly consists of acting out real-life roles with little integration of imaginary objects (Carlson et al.,1998). Finally, children with imaginary companions show a strong inclination towards engaging in fantasy-themed play and show higher levels of creativity than children who do not have imaginary companions (Hoff, 2005; Schaeffer, 1969; Taylor, 1999). Adults who recall having an imaginary companion as a child have also been shown to outperform those who do not on a variety of creativity indices (Gleason et al., 2003; Kidd et al., 2010; Taylor et al., 2003).

Summary

Pretend play is a pivotal activity for young children that can aid their cognitive, social, physical, and emotional development (Ginsburg, 2007). Indeed, engaging in pretend play has been linked to a range of emerging skills that go beyond those noted here, such as group work, self-advocacy, leadership, self-regulation, and negotiating tactics (Erikson, 1985; Hurwitz, 2002; Vieillevoye and Nader-Grosbois, 2008). Moreover, there are few behaviors that have returned such consistent, replicable, multilab associations as pretend play

has in regard to the wide range of key developmental domains. Of course, arguments about causation must be treated with extreme caution. But this should not undermine the importance of pretending to young children's development.

Conclusion

Instinctively, children like to play. They have an innate curiosity and a healthy sense for adventure, exploration, and excitement. Play is the early classroom, where children learn how to socialize, show initiative, negotiate conflicts, learn about rules, and communicate clearly. When their play begins to be populated by pretense, they are embarking on a journey with children the world over, a journey no other animal takes. Its expression may differ from child to child, its themes and structural components may change from community to community, but for many of the world's children pretending remains pervasive, intuitive, and engaging; and its absence (or limited expression) constitutes a marker of disrupted or atypical development. There are numerous domains or behaviors that are thought to be core components of young children's social and cognitive development (e.g., language and theory of mind). A claim can be staked that pretending is among the most crucial.

Abstract

Crime prevention is the act of stopping or reducing criminal activities, by either known or unknown offenders. This article explores various aspects of crime prevention, including the theoretical basis, as well as efforts by various criminal justice agencies, including law enforcement and correctional systems. Specific areas of interest, including substance abuse prevention and the role of firearms in crime, are also addressed.

Introduction

There is no singular definition of crime prevention, nor is there a singular means by which to prevent crime. One of the most concise definitions given by Steven Lab is, "Crime prevention entails any action designed to reduce the actual level of crime and/or the perceived fear of crime" (2006: p. 682). This definition would mean that crime prevention is inclusive of all crime reduction efforts. This may include those at the level of the criminal justice agencies, as well as by institutions, communities, and individuals. Any discussion of crime prevention should begin with the theoretical basis behind the concept. Additionally, the discussion also focuses on tactics by law enforcement, as well as those centering on sentencing and punishment, as well as specific efforts directed at firearms, drugs, and alcohol.

Theory of Crime Prevention

Crime prevention policies and programs draw from traditional criminological theories, such as learning theories and choice-based theories. Choice-based theories include deterrence, routine activity theory, and situational crime prevention. According to rational choice theory, individuals have free will to choose between criminal or noncriminal behaviors. Deterrence theory, the most prominent choice-based theory, is based on the idea that people engage in crime when the anticipated benefits of committing a crime outweigh the likely costs of crime. Conversely, the person is deterred from crime when the costs of crime outweigh the expected or predicted gains (Pratt et al., 2006). The quality of formal punishments is a key aspect of deterrence theory. In deterrence theory, there is an emphasis on swift, certain, and severe sanctions for criminal behavior. Deterrence presents a solid theoretical foundation for some policies and programs, and it offers a fairly straightforward solution to the problem of crime specifically to increase the likelihood of detecting a crime and strengthening the punishments associated with criminal behavior.

There are two forms of deterrence: general and specific. General deterrence seeks to prevent crime among the general population through the public awareness of both crimes and punishments. Specific deterrence seeks to prevent crime committed by those individuals who have already committed a previous offense. In theory, these offenders would not commit another offense because they experienced the pains of punishment meeting a threshold level of swift, certain, and severe penalties. For the prevention of crime, deterrence theory has a common sense appeal. Most people seek to avoid the painful experiences and variety of costs associated with formal sanctions by the criminal justice system.

Routine activity theory and situational crime prevention are more contemporary aspects of choice theory. Routine activity theory was developed by Cohen and Felson in 1979. The theory states that, a crime is more likely to take place when a victim motivated offender, and the absence of capable guardians converge in time and place. It is closely connected to rational choice since offenders still engage in decision-making processes whether to engage in crime but in a very specific context. Offender propensity to commit a crime may be constant yet specific places and contexts vary in terms of the temptations and controls present in the setting (Felson and Boba, 2010). The key component of the theory is the idea that crime can be controlled by manipulating the opportunity for crime by the strategic use of place managers who would have the responsibility for supervision of specific locations. Handlers provide additional supervision for those at risk of becoming an offender while guardians provide supervision for potential victims; a mentor provides an example for each category. Another example is the negative correlation found between the prosocial activities youths are involved in at the community level and their involvement in criminal activity. By engaging in law-abiding behavior, these youths are less likely to be both victims and offenders (McCall et al., 2012).

Likewise, situational crime prevention seeks to apply choice theory principles to very specific opportunities for crime (Clark, 1995). Crime prevention applications utilizing situational crime prevention emphasizes increasing the effort to commit the offense, increasing the risk of detection, reducing the rewards associated with the act, reducing the provocations to escalate a course of action, and remove excuses for offending (Center for Problem-Orientated Policing, 2011). Crowe (1991) has outlined the principles of crime prevention through environmental design (CPTED) to include the strategies of natural access control, natural surveillance, and territorial reinforcement. The strategies seek to reduce

opportunities for crime and also increase the risks of detection for offenders. Crowe (1991) notes that CPTED can be applied to problems associated with very specific settings such as restrooms in schools and convenience store layout and design. Using CPTED for the design of communities can have a positive impact on traffic patterns and related nuisance behaviors. Oscar Newman (1996) coined the term defensible space in the analysis related to the failure of the 2700-unit Pruitt–Igoe Housing Project.

Wilcox et al. (2013) provide a detailed discussion of the relationship between criminality as an individual propensity and the opportunities available to commit crime. They contend that the distribution of crime is driven by the perceived opportunities for criminal conduct in a specific context. Some places experience higher levels of crime attributed to the less guarded interactions of potential offenders and potential victims, the physical layout of a location with features that diminish the risks of detection and apprehension, as well as areas featuring lower levels of informal control. These factors operate independently and possibly interactively with one another, thus producing more opportunities for crime and less restraints in a more cumulative fashion.

In addition to traditional criminological theories, recent crime prevention strategies have adapted the medical model borrowed from the public health field. While deterrence theory has provided a historical foundation for criminal justice policies and crime prevention strategies, the medical model represents a fundamental shift from a reliance on responding to criminal events after their occurrence to a response strategy based on a true preventive strategy. The public health model emphasizes three approaches to crime prevention: primary, secondary, and tertiary prevention.

The medical model is best illustrated by society's potential responses to public health risks such as heart attacks, diabetes, or hypertension. Farrington (2000) notes that the public health model seeks to prevent the occurrence of these above-mentioned health ailments with a variety of strategies. A focus on emergency room treatment capacity, technology, and time to treatment intervention to improve the response to heart attack victims surely has a positive impact on life expectancy and outcomes although an exclusive reliance on such an approach fails to take into consideration other ways to reduce a person's initial risk of experiencing a heart attack. Individuals may benefit from making changes to their lifestyle, such as diet, exercise, and tobacco use, with a goal to reduce their improving their risk of health issues. Likewise, individuals who are at an increased risk to experience a heart attack may lower this risk with medication as well as additional lifestyle modifications.

Primary prevention takes a proactive stance to reduce the likelihood or severity of the targeted outcome prior to its development. Shader (2003) notes that primary prevention focuses on strengthening factors associated with abstaining from or avoiding criminal behavior. These factors are also known as resiliency factors. Primary prevention also seeks to reduce or minimize factors associated with an individual's likelihood to engage in crime; these factors are also known as risk factors. Farrington (2000) notes that a sufficient body of research permits policy makers to determine the relative cost-benefit impact of strengthening resiliency factors or address risk factors on the level of subsequent offending. This cost-benefit analysis allows policy makers to target factors with research supporting its effectiveness and also with the greatest potential cost savings.

Primary prevention emphasizes preventative efforts well before the onset of crime and delinquency. Regoli et al. (2010) identify prenatal programs, parenting programs, and preschool programs as model primary prevention efforts. Prenatal programs identify resource deficiencies for expecting mothers and target the delivery of services to improve the physical well-being of the mother and unborn child. These efforts seek to avoid or minimize negative factors for the baby such as low birth weight, neurological impairments, and exposure to various environmental toxins, which are factors associated with developmental and educational impairments. These factors are linked to poor school achievement and potential higher likelihood for involvement in delinquency in subsequent years.

While primary prevention programs impact a larger swath of the public, secondary prevention efforts target a narrower population. Secondary prevention focuses on individuals and places at an increased risk for crime and delinquency. Regoli et al. (2010) note the focus of secondary prevention is to reduce the prevalence, seriousness, or duration of crime and delinquency. Illustrating the concept of risk factors, Farrington (2000) identified nine risk factors for criminality among boys aged 8 to 10 years in separate studies in London and in Pittsburgh. These variables were "hyperactivity, poor concentration, low achievement, an antisocial father, large family size, low family income, a broken family, poor parental supervision, and parental disharmony" (Farrington, 2000: p. 5). The Juvenile Mentoring Program was developed to counter the development of risk factors among youths many of whom had attending risk factors (Novotney et al., 2000).

Tertiary prevention efforts seek to prevent future crime by those individuals who have already committed a crime. Prison-based programs best exemplify tertiary prevention programs. As is the case with primary and secondary prevention programs, not all tertiary programs produce their intended outcomes. The Scared Straight targeted youths who were seen by teachers, parents, and juvenile probation officers as likely to engage in more serious delinquency if not diverted from their current life trajectory. The Scared Straight program was made popular by a television documentary in 1978 narrated by Peter Falk. Finckenauer et al. (1999) contend that youths who experienced Scared Straight had worse outcomes in terms of delinquency than their counterparts in the control group. Klenowski et al. (2010) examined the research on juvenile awareness programs, the definition of which includes programs like Scared Straight. They examined eight evaluation studies of sufficient rigor and concluded that juvenile awareness programs are not effective in deterring juveniles. Critically, they note that youths who participate in these programs have worse outcomes than their peers who do not participate.

Police and Crime Prevention

Police agencies have incorporated crime prevention since the inception of policing in London in 1829. Sir Robert Peel

envisioned a mission for the London Metropolitan Police Department that centered on crime prevention. When crafting the mission of the London Metropolitan Police Department, Peel crafted nine principles detailing their mission and philosophy with crime prevention as a focal concern. These principles were

> The basic mission for which the police exist is to prevent crime and disorder.
>
> The ability of the police to perform their duties is dependent upon the public approval of police actions.
>
> Police must secure the willing co-operation of the public in voluntary observation of the law to be able to secure and maintain the respect of the public.
>
> The degree of co-operation of the public that can be secured diminishes proportionately to the necessity of the use of physical force.
>
> Police seek and preserve public favour not by catering to public opinion, but by constantly demonstrating absolute impartial service to the law.
>
> Police use physical force to the extent necessary to secure observance of the law or to restore order only when the exercise of persuasion, advice, and warning is found to be insufficient.
>
> Police, at all times, should maintain a relationship with the public that gives reality to the historic tradition that the police are the public and the public are the police; the police being only members of the public who are paid to give full-time attention to duties which are incumbent upon every citizen in the interests of community welfare and existence.
>
> Police should always direct their action strictly towards their functions, and never appear to usurp the powers of the judiciary.
>
> The test of police efficiency is the absence of crime and disorder, not the visible evidence of police action in dealing with it. (Nazemi, 2009)

Preventive patrol is the primary technique used by the police to prevent crime. This focus, which started with the formation of early police departments, has incorporated motorized patrol, foot patrol, improved dispatch, and differential response to calls to aid in maximizing police visibility and response. The reliance on preventative patrol would remain untested until the Kansas City Patrol Study challenged the basic assumption of the effectiveness of preventive patrol (Kelling et al., 1974), which concluded increased levels of preventive patrol had no effect on crime and victimization.

Subsequent research by Sherman and Weisburd (1995) sought to address a methodological issue present in the Kansas City Patrol Study. They note there was a built-in bias toward a finding of no difference between the levels of patrol since comparisons across only 15 police precincts. To remedy this issue, Sherman and Weisburd used 110 hot spots in the city of Minneapolis, which generated a disproportionate amount of calls for service in the city. The 110 locations were divided randomly into an experimental group and a control group. In the experimental group of hot spots, there was a target goal of 3 h of total police presence between the hours of 11 a.m. to 3 a.m. The hot spots in the experimental group received roughly double the amount of police presence as the control group. Officers could engage in a variety of activities while at the hot spot but the primary goal was for officers to stay at the hot spot for a relatively short period of time and return frequently to the location.

Sherman and Weisburd (1995) report a modest deterrent effect using directed police patrols in crime hot spots. They describe the impact as microdeterrence effect since the impact had a small geographic application and the displacement of crime was not tested. Displacement of crime refers to the movement of crime from one location, in this case the physical area receiving a fairly significant dosage of police presence, to another area. In effect, there is potential for motivated offenders to seek criminal opportunities in other areas with less official supervision and presence. Sherman and Weisburd note the optimal length of the police presence in the directed patrol is about 12 min. They note the impact of directed police patrol on social disorder. The results indicated that social disorder was present in 1 of every 50 encounters on the street in the experimental group while social disorder was present in one of every 25 encounters on the street in the control group.

Smith and Scott (2013) provide an extensive discussion of the historical progress of crime prevention strategies of police. They note that modern crime prevention efforts can be grouped into three broad categories of activities: community policing, problem-orientated policing, and intelligence-led policing. They note that community policing has become ubiquitous but the proliferation of the related tactics associated with community policing has come at the expense of clarity of the concept. Enduring concepts of community policing include improved collaboration between the police and the public in developing police priorities and an emphasis on problem solving. Problem-orientated policing and intelligence-led policing likewise focus on solving problems but can be used within the traditional style of policing.

Sentencing and Punishment

At the very core of criminal sentencing philosophies is the idea of crime prevention. When an offender is given a sentence, it is believed that not only will he or she not commit crime while serving their prescribed punishment, but beyond that time frame as well. A wide range of punishments can be given, depending on the severity of the offense, ranging from a citation to capital punishment.

Intermediate sanctions are those that are the most commonly used, and often include some level of community supervision to prevent the offenders from recidivating. Community supervision includes probation and parole, as well as additional methods of control, such as electronic monitoring or home confinement. At year end in 2011, the United States had approximately 4 814 200 individuals on community supervision (Maruschak and Parks, 2012). Because the likelihood of recidivism is the greatest immediately upon release from jail or prison, the most intensive forms of

community supervision generally occur at the beginning of their supervision period (Petersilia, 2003).

In the United States, offenders sentenced to serve a term of incarceration are given either indeterminate or determinate sentences, depending on the state in which they live. Most states have moved toward the determinate sentencing system, which allocates a specified length of time to be served for each crime, as opposed to the indeterminate sentencing system, which offers a range of time to be served, depending on factors such as efforts toward rehabilitation. Some states also prescribe mandatory minimum sentences. Mandatory minimums are designed to deter potential offenders due to the severity of the punishment. For instance, some states have instated three strikes laws, which mandate that after three felonies, offenders are given mandatory life sentences. While most states stipulate these felonies must be violent, California does not differentiate between violent and nonviolent felonies.

At the end of 2011, there were 2 239 800 offenders serving time in either jails or prisons (Glaze and Parks, 2012). While incarcerated, some inmates are provided opportunities for rehabilitation, education, and vocational training, all of which are designed to prevent recidivating upon their release. However, due to increasing jail and prison populations and lack of financial resources, many of these recidivism reduction programs have been either drastically reduced or eliminated (Petersilia, 2003).

Capital punishment is the most severe penalty that can be levied against an offender. Worldwide, 58 nations list death as a potential punishment, including the United States, where it is reserved for murder with aggravating circumstances. Although these circumstances vary by state, some commonalities include murder of a law enforcement officer, murder of young victims, murder for remuneration, and murder during the commission of other felonies.

As a crime prevention tool, specific deterrence is achieved by capital punishment. Once an offender has been executed, he or she no longer has the opportunity to commit future crimes. General deterrence is more difficult to achieve. The basic tenets of general deterrence (the punishment must be severe, certain, and swift) cannot be adequately achieved under the current system. Inarguably, capital punishment is a severe penalty. However, the possibility of not being apprehended, plea bargains, and options for lesser sanctions reduce the certainty of the punishment. The swiftness of the death penalty is reduced by the lengthy trial process, as well as the time spent on death row, which averages about 15 years (Time on Death Row).

Guns and Crime

The relationship between firearms and crime is a tenuous and complex one. The United States has high rates of gun ownership, and correspondingly high rates of gun-related crime. Firearm ownership is the most prevalent in the southern regions of the United States and among white males (Cook and Ludwig, 1995; Spano et al., 2008; Wyant and Taylor, 2007).

Firearms are used in about 8% of violent crimes, including 28% of robberies and 5% of assaults (Truman and Rand, 2010). Handguns are the most prevalent weapon used in homicide, followed by other guns, knives, other weapons, and blunt objects (Cooper and Smith, 2011). An argument or assault is more likely to be fatal if a firearm is present (Hepburn and Hemenway, 2004).

These and similar statistics are often cited to increase gun control policies. However, some argue that because many of the firearms used to commit crime are not obtained legally, gun control is simply more successful at keeping firearms out of the hands of the noncriminogenic population. For instance, the Brady Bill of 1993 attempts to prevent the sale of the firearms to those who are the most likely to use them for commission of a crime. The main tenets of the bill instituted a background check for all firearm purchases, as well as a 5-day waiting period.

Most firearms that are used to commit a crime are not purchased legally (Piquero, 2005; Wright and Rossi, 1986). Many are obtained through friends or family, or through 'straw purchasers,' who legally purchase the guns and then sell them on the black market. These illegal transactions often occur quickly after the legal purchase, especially in the case of semiautomatic and large caliber guns (Brandl and Stroshine, 2011). Additionally, guns may be stolen during household burglaries or other property crimes. Annually, an average of 232 400 firearms are reported stolen (Langton, 2012). Many of these firearms will be used to commit crime, or be sold on the black market to those who cannot purchase a gun legally.

Thus, it seems that those who want to obtain firearms will do so, through either legal or illegal means. Some scholars, such as John Lott (2000) argue that by increasing the prevalence of firearms among the noncriminogenic population, crime can be better prevented. This is especially true if the weapons are concealed, as the criminals will be unaware of who is armed, theoretically deterring them from crime regardless of whether their proposed target is armed.

Other initiatives have been implemented to decrease the presence of firearms among criminogenic populations. For instance, gun buyback programs provide gift cards in small amounts in exchange for firearms from neighborhood residents. These programs had little impact, if any, on gun violence (Callahan et al., 1994). Project Exile is another initiative, which gives felons in possession of a firearm a mandatory minimum sentence. There have been mixed reports on the effectiveness of this initiative.

Drugs and Alcohol

According to the National Institute on Drug Abuse (2012), in 2011, about 22.5 million Americans aged 12 years and older used illicit drugs in the past month. Marijuana is the most commonly used drug, followed by psychotherapeutics, cocaine, hallucinogens, inhalants, and heroin. Additionally, more than half of those surveyed reported being current alcohol drinkers, with about $^{1}/_{4}$ of respondents reporting binge-drinking behaviors.

Prevention of drugs and alcohol is difficult for several reasons. Alcohol is legal, and is controlled in terms of creating laws in limiting the sale to minors. Marijuana is legal in a few states, but is illegal in most. Prescription drugs are legal to those who they are prescribed. The partial legality of these substances

make them difficult to monitor and control, especially as black markets are created for them.

The use of most substances, legal or not, generally occurs in private residences, making it difficult to prevent or monitor the individuals using them. Moreover, with the exception of drunk or drugged driving, or other crimes occurring in conjunction with these offenses, they are generally considered victimless crimes. In the absence of a victim, not only are they unlikely to be reported, but they also may be low on the priority list for law enforcement, especially if there is a relatively large number of violent or property crimes with which they must contend.

Despite these obstacles, there are initiatives in place to try to prevent drug- and alcohol-related offenses. For instance, to reduce Driving Under the Influence (DUI) or Driving While Intoxicated (DWI) incidents, most states enforce a blood alcohol content level of less than .08. In order to deter individuals from driving under the influence, police checkpoints are often set up at roadblocks.

Other methods involve preventive education. Perhaps the most well known of these is Drug Abuse Resistance Education (DARE), which began in the 1980s. Generally, DARE brings law enforcement officers into elementary or middle schools to provide drug education to students, who in turn make a pledge to desist from drugs. Many studies have cited DARE's ineffectiveness to decrease drug use among participants. Some studies have indicated that substance abuse among DARE participants actually increased after being exposed to the program (Sherman et al., 1998). The DARE program recently adopted the 'keepin' it REAL' program. This revision includes teaching effective communication strategies, as well as considering diverse cultural and ethnic audiences (Hecht et al., 2010).

Another tactic used for prevention is the use of drug treatment programs. Because of increased sentences directed at substance abusers, they comprise approximately 56% of federal and 20% of state inmates (West and Sabol, 2010). Although only a small number of those who need treatment will receive it, primarily due to financial restraints (Petersilia, 2003), less expensive alternatives, such as those delivered in group or therapeutic community settings, have had positive results in preventing future substance abuse (Mitchell and MacKenzie, 2003).

Conclusion

Just as there are many causes of crime, there are many ways in which crime can be prevented. Preventing crime and delinquency often involved multiple agencies and individuals. Criminal justice agencies, such as police, courts, and corrections, all play an important role in prevention. Communities also play an important role by being proactive with efforts such as neighborhood watch engaging in collective efficacy. Individuals are also responsible for crime prevention. This can be accomplished by making their physical spaces less susceptible to crime (for example, by installing security systems or locking the doors to their homes), and avoiding situational crimes (for example, by not being in high-crime areas). Despite the numerous efforts put forth in order to prevent crime, it should be remembered that not all crime is preventable.

Abstract

This article presents an overview of the history of prevention science from its conceptual foundations and definitions through its development as a well-established and extremely productive discipline. Effective approaches for program dissemination and evaluation are presented. Other topics covered include the relationships between risk and resiliency, prevention versus promotion, and program implementation versus program innovation. Current efforts in assessing cost-effectiveness, the cultural relevancy of prevention programs, and the role of prevention science in informing public policy are explored. Examples of effective prevention and promotion programs are included throughout the article.

In 1962, David Weikart, the director of special education for the Michigan, Ypsilanti Public School District, came up with an ambitious plan. A large portion of the children in his district came from disadvantaged homes, and many did not start school until the first grade. The director knew that these children were faced with an elevated risk of school failure and other negative outcomes compared to children born in more affluent circumstances. His plan was to prevent those negative outcomes by providing the children with a high-quality, academically based preschool program. This was the start of the Perry Preschool Program, one of the longest running primary prevention programs in the United States.

Over the next 5 years, 123 children were recruited into the project when they were 3 or 4 years old. Half of the children attended the preschool program; the other half did not. The initial evaluations of the program showed higher intellectual performance among preschool participants compared to the control group. These effects, however, diminished somewhat over time, suggesting that the positive effects of the program were only short-lived. But at age 10, the researchers found something surprising, the positive effects seemed to be amplifying rather than diminishing over time. Program participants were significantly less likely to have been held back a grade or placed in special education than children in the control group. At age 15, program participants demonstrated higher academic achievement than those in the control group, and by ages 19 and 27, program participants were showing significantly higher educational achievement, employment rates, earnings, and rates of home ownership, and lower rates of criminal behavior and single parenthood than the comparison group. Later evaluations found that these positive effects continued until the participants were 40 years old and concluded that the general public gained $12.90 in return for every $1 spent on the program (Schweinhart et al., 1993, 2005).

The results of this study have had an immense effect not only on the public recognition of the benefits of high-quality preschool programs, but also on the field of prevention science as a whole. In this article we will give a brief overview of the history of prevention science, focusing on the extensive development of the field in the past 50 years. In particular, we will address current theory and research considering: (1) the relationship between the concepts of prevention and promotion; (2) effective approaches for disseminating programs, including issues of fidelity and context-based innovation; (3) the central role of program evaluation in implementation; and (4) assessing cost-effectiveness.

Conceptual Foundations of Prevention Approaches

Contemporary approaches to prevention draw upon a range of intellectual backgrounds and disciplines. In this section we briefly review major schools of thought and leading advocates for prevention.

Public Health Models for Prevention

Systematic investigation and intervention to control the spread of contagious diseases, such as cholera, polio, or tuberculosis, date back to the mid-nineteenth-century England and physician John Snow (Kloos et al., 2012). Identification of risk factors (e.g., using water from a specific neighborhood well) and changing environmental conditions (e.g., removing a pump handle, better sanitation) have become a cornerstone of public health approaches to prevention. These early efforts established principles common to most prevention efforts. First, it is assumed that the problem of concern will be distributed among a specific population or specific area. This distribution needs to be understood as a rate of exposure or vulnerability. New cases of the problem can be tracked as the *incidence* of a problem and compared across time and space. The overall rate of those who have the problem establishes the *prevalence* of that problem in a specific region. Second, it is assumed that science can identify factors that increase an individual's risk to developing the problem. These factors may be environmental, individual, or result from an interaction of individuals in particular environments. When risks are not well understood, more study is needed. Third, once risk can be identified, broad-scale efforts are needed to identify those who are at greater risk. Fourth, effective interventions need to be

developed to help people avoid the risk through changing environmental conditions (e.g., draining swamps to reduce exposure to mosquitoes with malaria) or boosting individuals' capacities to fend off risk (e.g., a policy of early vaccination). From a public health perspective, individual treatment may be inefficient to address large areas of need, not timely enough, inefficient, or too costly. Although it may not be possible to completely avoid new cases of a problem in a population, there is value in greatly reducing the number of people affected.

Introducing Prevention to Mental Health

Mental health treatment had long included goals of reducing stress, but a conceptual framework for systematic prevention was largely lacking until the mid-twentieth century. Public health and community psychiatry helped to bridge these notions and achieve goals for which progress had been so limited. Nicolas Hobbs (1964) proposed that a 'third mental health revolution' occurred when prevention of dysfunction was introduced as a goal of mental health systems. As conceived by Hobbs and his contemporaries, community mental health would provide services in the local contexts where people spent their daily lives, and if possible, to avoid problems becoming episodes of mental illness that required hospitalization. Hobbs' revolution was built, in part, upon two observations in the late-1950s. First, one of the influential reports from the U.S. Joint Commission on Mental Illness and Health documented that we will never be able to train enough mental health professionals to meet the expressed need for traditional individual-oriented mental health services (Albee, 1959). Second, persons of lower socioeconomic class were more likely to receive hospitalization (e.g., psychotropic drugs or electroshock) and less access to effective outpatient care (Hollingshead and Redlich, 1958). Thus, new models of service were needed to prevent problems where possible. As proposed by Hobbs, a strategy of prevention included both pragmatic grounds (i.e., meeting the expressed need for mental health services) and a values-based concern about providing greater access to effective mental health care, especially to those who did not have resources to seek their own private treatment. This blending of pragmatics and values leads to an ideology of prevention that seeks to avoid illness rather than only ameliorate it.

Articulating Strategies for Prevention

Gerald Caplan's (1964) *Principles of Preventive Psychiatry* created an elegant framework for promoting prevention in mental health that was both parsimonious and generative. He provided practical examples of how ideas from sociological and epidemiological analyses of disadvantage and risk could be translated into mental health practices.

Tertiary Prevention

This level of prevention targets people who already have an illness or problem. The focus of tertiary prevention is to reduce the rate of existing disorders in a community, notably by targeting the duration and associated conditions that can exacerbate and prolong episodes of illness. Like public health models, Caplan maintained that the "community is the client." Prevention must include large-scale programs to change social conditions for large programs of persons with a problem (e.g., housing and employment programs as policy for all persons with disabilities). Caplan distinguished this from rehabilitation, which he defined as efforts to work with an individual client on her/his deficits. In mental health, tertiary prevention guides efforts to go beyond custodial care to address social conditions and quality of services to keep people functioning in communities. An early example of a tertiary prevention program is the Community Lodge program, which is designed to prevent the rehospitalization of adults living with serious mental illness (Fairweather, 1979).

Secondary Prevention

This approach seeks to lower the number of cases of a problem for a population determined to be at increased risk. Typically, this is accomplished by early identification of risk and interventions to alter the influence or exposure to factors that put people at greater risk (e.g., building individuals' capabilities, removal of stressors). As prevention has been practiced, this level often focuses on children and youth, identifying situations and vulnerabilities that could lead to problems later in life. Alternatively, early detection of risk can mean early screening and diagnosis of premorbid illness (e.g., colon cancer screening, mental health screenings in work places or schools). This early identification of heightened risk does not necessarily lead to individual treatment. Rather, these approaches often involve teaching skills or applying additional resources to promote functioning. This approach to prevention requires reliable identification of risk factors and potent interventions to reduce risk.

Parenting programs for families with young, highly oppositional children are an example of secondary prevention. The children in these families are already displaying behaviors that are not only considered problematic in themselves, but are also predictive of more serious problems later in development (Patterson et al., 2010; Webster-Stratton, 1984).

Primary Prevention

While the first two levels of Caplan's approach to prevention could be viewed as extensions of traditional mental health services, primary prevention introduced radically new ways of thinking about promoting mental health and well-being. "(Primary prevention) seeks to reduce the risk for the whole population, so that, although some may become ill, their number will be reduced. It thus contrasts with individual patient-oriented psychiatry, which focuses on a single person and deals with general (community) experiences only insofar as they are combined in his unique experience" (Caplan, 1964, p. 26). This emphasis on addressing risks to health of a whole population *before* signs of risk for individuals are identified moved mental health services away from primarily focusing on individuals' deficits or potential deficits. For Caplan, primary prevention included assessment of health and conditions that promote health and well-being.

Programs to increase women's access to and use of prenatal care (Edgerley et al., 2007), efforts to ensure that children do not begin smoking cigarettes (Jason et al., 1999), and programs to increase the use of safe sex practices to prevent sexually

transmitted disease (Lykes et al., 2007) are all examples of primary prevention programs.

Applying Models for Prevention beyond Mental Health

While Caplan primarily focused on mental health, his ideas for prevention have been influential outside of psychiatry and related professions. His insights into primary prevention, in particular, have led to efforts to identify conditions that put people at risk for a variety of life problems and attempts to prevent them for entire populations (e.g., substance abuse, teen pregnancy, exposure to violence).

Barbara Snell Dohrenwend (1978) and George Albee (1982) advanced the field by proposing heuristics to conceptualize both potential risk and resources to avoid the development of problems. First, they helped expand how risk was conceptualized. Risk factors could be either proximal or distal to persons' experiences. Furthermore, risks could be physiological or psychological, social, or environmental. Similarly, potential protective factors could be identified in each of these domains. Summarized in Albee's prevention equation, cumulative risk for an individual developing a particular problem could be viewed as the numerator of an equation where the denominator represents collective resources to resist developing the problem.

$$\frac{\text{Stress} + \text{Physical vulnerability}}{\text{Coping skills} + \text{Social support} + \text{Self-esteem}}$$

These frameworks identify several potential targets of intervention to reduce risk or to promote coping and competence. Maurice Elias (1987) applied this framework to address conditions associated with the development of behavioral, emotional, or social disorders in populations rather than just in individuals. This extended prevention formula targets changing environmental conditions (e.g., families, schools, organizations, neighborhoods, and societies) rather than focusing solely on changing individual behavior or exposure to risk. These models helped expand the range of preventive strategies that might be used for intervention (e.g., health promotion, skills training, environmental control, social policy) and create opportunities to apply preventive strategies to a wide range of social problems as well as health concerns.

Pandisciplinary Approach to Prevention

Thirty years after Hobbs called for prevention to be integral to mental health care, the Institute of Medicine (IOM) issued a consensus statement promoting prevention approaches across disciplines. This report introduced a new framework for classifying preventive interventions: universal, selective, and indicated prevention (Mrazek and Haggerty, 1994). This framework seeks to promote prevention of health problems widely and to promote collaboration across disciplines. Below, we briefly describe each of these three approaches.

Universal preventive interventions are utilized for everyone in a given population group to promote well-being or avoid problems. They are usually implemented for populations without specification of special risk but avoid risks common to all (e.g., using barriers to blood-born pathogens, washing hands). Universal prevention is similar to Caplan's model of primary prevention. *Selective preventive interventions* are intended for those at above-average risk for developing disorders. The risk may be based on exposure to environmental stressors (e.g., neighborhood crime, pollution) or individual factors (e.g., cognitive vulnerabilities, health conditions). In selective prevention, indicators of risk have been documented as being related to etiologies of disorders but are not criteria for diagnoses of particular disorders. *Indicated preventive interventions* are directed toward individuals who are determined to be at high risk for developing a disorder. Unlike selective prevention, indicated prevention is used when persons show early symptoms of the disorder but their condition does not yet meet diagnostic criteria. Caplan's concept of secondary prevention appears to encompass both selective prevention and indicated prevention as proposed by the IOM.

While the IOM model has promoted prevention as a strategy to address health concerns in a variety of disciplines, it has been critiqued as too narrowly focusing on strategies to address individual deficits. For example, preventive efforts centered on preventing negative childhood health outcomes will not encourage positive development or promote normal development of children (Weissberg et al., 2003). This individual focus can overlook environmental conditions and raises the potential to overlook environmental factors in health problems (Wandersman and Florin, 2003). Although the foci and strategy of prevention may be debated by those from different disciplines, it is clear that prevention as a strategy for intervention and prevention science was well-established at the start of the twenty-first century.

The Development of Prevention Science

Prevention science encompasses a number of different areas of research, including research regarding the etiologies of specific physical, behavioral, or emotional problems and the development of effective interventions for particular disorders. An important emerging area of research focuses on understanding the science of implementing preventive interventions. As with many fields, there are debates about the merits of different emphases, with some arguing that additional research into etiologies is not necessary to develop effective interventions, or even that there has been a wealth of evidence-based interventions developed and the current critical need is to better understand the science of implementing those successful interventions.

Two important areas of discourse in prevention science are the concepts of prevention of disorders versus the promotion of wellness and the relationship between risk and resiliency.

Prevention and Promotion

While a range of prevention and promotion strategies are generally acknowledged in prevention science and prevention policy, the relative emphases on the prevention of disorder and the promotion of wellness and competence can conflict when considering the commitment of resources to each. Advocates of each view are ardent in their preferences for the focus of prevention science, with those focusing on prevention arguing that we have developed a great deal of knowledge regarding

how to prevent specific disorders and those focusing on wellness promotion arguing that the absence of a specific disorder does not ensure psychological well-being. These advocates point to an extensive knowledge base that has developed regarding the promotion of sound health and social competence (Kloos et al., 2012).

As this discussion illustrates, the goals of preventing specific disorders and promoting wellness and competence are not necessarily mutually exclusive. The implementation and effects of these strategies may be very similar in particular circumstances. For example, the prevention of obesity and the promotion of physical activity may use similar interventions and have similar outcomes.

Adding to the complexity of this debate are the related recent findings that the complete results of prevention efforts cannot be known without the collection of longitudinal data, stretching over decades. While these data are difficult to collect, there is evidence of the results of some prevention programs amplifying over time, such as in the Perry Preschool Project, or even cascading to produce benefits entirely unpredicted by the original program designers.

For example, recent research regarding the long-term effects of parent-training programs has found results as unexpected as improved educational, occupational, and income levels for mothers (Patterson et al., 2010). These cascading beneficial effects make sense theoretically when you consider the relationship between prevention and promotion. Parent-training programs such as the one developed by Patterson and his colleagues are designed to prevent the long-term problems associated with the early onset of conduct disorders in children. Extensive research has shown that these problems can be prevented by training parents to interact with their children in new ways, eliminating the coercive patterns of interaction generally found in those families. Patterson et al. hypothesize that teaching mothers to relate in positive noncoercive ways with their children also results in healthier (and happier) relationships with romantic partners, friends, colleagues, and supervisors. In other words, the same skills that help mothers to prevent serious behavior problems in their children also serve to promote positive relationships in other parts of their lives.

A related discussion in prevention science is the increased understanding of the relationship between risk and resiliency.

Risk and Resiliency

The concept of resiliency has gained immense importance in prevention science since it was first introduced by Emmy Werner as the central finding in her 40-year longitudinal study on the island of Kauai. Werner and her colleagues followed all 698 children born on the island in 1955. Of those children, 30% were exposed to one or more risk factors in early infancy, including complications surrounding the pregnancy and birth, poverty, family disruption, parental psychopathology, and mothers with limited education. Two-thirds of the children exposed to four or more of these risk factors experienced significant difficulties in childhood or adolescence. The negative effect these risk factors had on child development was clearly evident in the research findings.

But that was not the finding that was most surprised and impressed Werner and her colleagues. They were struck by that remaining one-third, the children who were exposed to four or more risk factors but still developed into 'competent, confident, and caring adults' (Werner, 1996). Subsequent research has identified numerous factors associated with resiliency, which can be usefully grouped into categories of individual differences, relationships, and community resources and opportunities (Masten and Powell, 2003).

Risk factors in child development had been identified and debated for decades before an understanding of resiliency factors began to emerge. It is only after solid research on both risk and protective factors became available that it was possible to begin the development of comprehensive approaches to promote positive development. Examples of such approaches include The Search Institute and Communities That Care. While there are some differences between the programs, both work on a community level, on the basic assumption that a community that actively reduces risk factors in child development and strengthens protective factors will support healthy development among all its children. These programs explicitly work to prevent problems through the promotion of wellness in child development.

Each program works by educating community leaders about risk and protective factors, and then helping them to assess the presence or absence of those factors in their communities, investigate model programs for reducing risk factors and increasing protective factors, and implement and evaluate those programs. These programs have been demonstrated to be quite successful. A cost-effectiveness evaluation of community-based programs in Pennsylvania implemented largely through the Communities That Care model demonstrated returns of up to $25 for every dollar invested by the Commonwealth. A single program could generate up to $130 million dollars in savings (Jones et al., 2008).

Methodological Challenges

Developing, implementing, and assessing prevention programs present several methodological challenges for the field of prevention science. While assessing the effectiveness and cost-effectiveness of the prevention efforts can be difficult, these goals can be largely met through established methodologies. That is not necessarily true for the challenges inherent in effectively implementing and disseminating programs to communities.

Assessing Effectiveness

Proverbs and fables from around the world testify to our belief in the effectiveness of prevention efforts. But this deep cultural belief in the effectiveness of prevention efforts is no substitute for empirical evidence. Providing that evidence presents several methodological challenges, both theoretical and pragmatic in nature.

The basic challenge is central to the whole concept of prevention. Prevention programs are intended to prevent something from occurring and it is difficult to demonstrate that an event that would have occurred without intervention was

prevented from occurring. Often the event to be prevented and the intervention designed to prevent it occur years or even decades apart, such as the prevention of adult criminal behavior through the provision of high-quality day care.

At this point there is a great deal of evidence demonstrating that effective prevention programs have been developed for a wide variety of topic areas. For example, meta-analyses of prevention programs aimed at children have shown efficacy for programs aimed at teen pregnancy, school bullying, childhood obesity, childhood and adolescent depression, child and adolescent drug abuse, programs implemented in infancy or early childhood, mentoring programs, and school-based programs to enhance social–emotional learning skills (Durlak and Wells, 1997, 1998; DuBois et al., 2011; Weissberg and Durlak, 2006).

The state of the field is also such that there is excellent information regarding best practices to ensure that a prevention program will be effective. Programs should be theory driven and evidence based. They should be comprehensive, including multiple interventions in multiple settings to achieve interrelated goals. They should be appropriately timed, of a sufficient dosage to have a lasting effect, and be socioculturally relevant. Effective programs include a strong behavioral component, teaching relevant skills and providing opportunities to practice those skills. They should focus on developing positive relationships, and instituting second-order change by fostering planned changes in institutions, communities, and policies. Finally, effective prevention programs provide significant support for the staff members implementing the program and include a planned program evaluation component (Nation et al., 2003).

Assessing Cost-Effectiveness

Many prevention programs are quite inexpensive to implement, such as mentoring programs that rely largely upon volunteers. Even these inexpensive programs still come with some monetary costs, and for some programs those costs are considerable. For example, Nurse Home-Visiting programs that begin prenatally have been shown to increase prenatal care, decrease low-birth-weight babies, improve parenting, and have long-term positive effects on various aspects of child development (Howard and Brooks-Gunn, 2009). But these programs are quite expensive to implement, since they utilize nurse practitioners and other professional or paraprofessional support staff.

These differences in cost raise two important questions for prevention science. First, if there is more than one prevention intervention or policy that has demonstrated effectiveness in the area of interest, which will achieve the program goals for the lowest cost? Second, at what point do the monetary benefits of a prevention program exceed the costs of the program? The first question can be answered through a cost-effectiveness analysis and the second through a cost-benefit analysis.

Cost-effectiveness analyses compare multiple prevention programs to determine which program results in the greatest benefit for the least cost. An early example is the analysis by the RAND Corporation comparing California's three-strikes law to four evidence-based programs that prevented criminal behavior. The analysis found that two of the four programs were more cost-effective than the three-strikes law (Greenwood et al., 1998).

Cost-benefit analyses compare the cost of providing a prevention program with the cost savings that are ultimately achieved by that program. Essentially, it is estimating the return on the investment in a prevention program. Multiple studies demonstrate that even relatively expensive programs can demonstrate significant returns on the public investment, in the range of $10 returned for every dollar spent and higher (Jones et al., 2008; Reynolds et al., 2011; Schweinhart et al., 2005).

These analyses face many challenges. While estimating the cost of programs may be relatively simple, estimating the savings generated from those programs is not. Many of the cost savings come from decreased use of the criminal justice system, special education services, and income support programs. But in addition to those savings, there are also returns to society in increased employment, income, and income tax revenue. Predictive models, which estimate these returns to society going forward, are obviously much more tentative than longitudinal studies that derive data from the actual life experiences of their participants. While these types of longitudinal studies are difficult, time-consuming, and rare, it is exactly these studies that are documenting some of the highest rates of return for prevention programs (Reynolds et al., 2011; Schweinhart et al., 2005).

Program Implementation and Dissemination

There is a major gap between prevention science research and the programs that are commonly occurring in schools and community settings. For example in 2011, a report of a national survey of 2500 public school districts and 5847 schools found that many schools offered crime prevention and substance-abuse prevention programs (U.S. Department of Education, 2011). However, only a small proportion (7.8%) was evidence-based programs and only a minority was implemented with minimal standards of fidelity. Therefore, only 3.5% were both research based *and* implemented with fidelity. This clearly illustrates the importance of implementing with quality and disseminating information about evidence-based programs with appropriate support for implementing with quality. In 2008, Wandersman and colleagues collaborated with colleagues at the Centers for Disease Control and Prevention (CDC) to develop the Interactive Systems Framework for Dissemination and Implementation (ISF) (Wandersman et al., 2008) to help bridge research and practice. The ISF describes the three systems listed below, and their interconnections, that are crucial for bridging research and practice.

Synthesis and Translation System

There are numerous articles in many journals about a topic area (e.g., childhood obesity). For the information to be widely used in practice, there needs to be a synthesis of the literature (e.g., literature reviews, meta-analyses). However, the synthesis articles that result rarely come with 'how-to's' for the practitioner. Therefore, it is necessary to have user-friendly translations of the materials.

The Delivery System

The Delivery System consists of the organizations and collaborations that provide services to residents, consumers, students, etc. (e.g., schools, mental health agencies, Boys and Girls Clubs). These organizations have general capacity (e.g., number and type of personnel, organizational structure, fiscal, and technical resources) and must acquire the capacity to implement an intervention with quality. The premise is that the Synthesis and Translation System will provide evidence-based information about what to do (and not to do) in order to achieve positive health and human service outcomes. However, as the 2011 study suggests – evidence-based programs implemented with quality are a small minority of the programs (U.S. Department of Education, 2011). It is hypothesized, and there is evidence (e.g., Joyce and Showers, 2002) that support in the form of training and technical assistance/coaching helps lead to better quality implementation.

The Support System

The third system in the ISF is the Support System. Often, there are individuals or organizations that provide support (e.g., tools, training, technical assistance) to assist the Delivery System in developing the capacity to implement programs with quality. Working with the idea that if it is important to be evidence-based about programs, Wandersman et al. (2012) describe the importance of delivering support in an evidence-based/evidence-informed way.

Emerging Directions

In addition to the ongoing issues discussed above, there are several emerging topics in the field of prevention science that warrant exploration. Three of them will be discussed here: the relative emphasis on program fidelity versus program innovation, the importance of incorporating cultural knowledge and values into prevention programming, and the relationship between prevention science and public policy.

Program Fidelity versus Program Innovation

A major discussion in the field of prevention science is the dynamic tension between the need for fidelity in the implementation of programs that have demonstrated effectiveness, and the benefits of modifying model programs to better fit local context. The importance of program fidelity has been well documented and the push for evidence-based programming has a solid empirical basis. But an insistence on strict adherence to every aspect of model programs has its own drawbacks. Must every aspect of a program be faithfully reproduced in order to ensure the replication of beneficial effects? Research suggests that this is not the case, and that in fact there are *core components* of interventions that drive the effectiveness and must be carefully replicated (Elias et al., 1997).

Research identifying those key components is a particularly important goal for prevention science since there are also excellent reasons to encourage innovation in program implementation (Durlak and DuPre, 2008). Programs that are adapted to address the specific contexts in which they are implemented are more likely to be successful, and these types of innovations, if done carefully and with documentation, can lead to important advancements in prevention science. The Interactive Systems Framework for Dissemination and Implementation described earlier provides one avenue to ensure that programs are implemented with a high level of quality, even when those implementing the program choose to make targeted adaptations.

One area of particular importance for program innovation has to do with cultural context.

Cultural Diversity

In the field of prevention science, there is a growing emphasis on the adaptation of preventive interventions to diverse communities. The American Psychological Association's recently adopted Guidelines for Prevention (2013) encourages, for example, the use of "socially and culturally relevant preventive practices adapted to the specific context in which they are implemented" in its set of nine guidelines, a recommendation that is second only to the use of evidence-based interventions. Research has demonstrated that effective prevention programs attend to relevant cultural and contextual factors, and that successful implementations of evidence-based programs frequently include significant adaptations (Durlak and DuPree, 2008). Implementation of evidence-based interventions in different cultural contexts is understood by many in the field to be the next research frontier (O'Connell et al., 2009).

In countries around the world, populations are becoming increasingly diverse. Societies are also growing more aware of social inequities and how they lead to educational and health disparities marked by race, gender, social class, culture, ethnicity, sexual orientation, ability/disability, age, and religion. Diversity within and between communities is an important part of understanding when and where particular preventive interventions may be most effective. Attention to diversity also helps prevention researchers and practitioners to acknowledge their own cultural worldviews, including individually held values and collective professional values. What one chooses to study, what one believes needs preventing, and how one chooses to intervene depend upon values, assumptions, and definition of the problem to be prevented. Problem definition also affects how successful program outcomes are defined and who decides what counts in determining program success.

Grappling with these issues of problem definition and valued outcomes in a successful cultural adaptation requires collaboration with community members affected by the target intervention. Community collaboration also improves prevention research and evaluation – enhancing research questions, helping to address research challenges that emerge, and enhancing the usefulness of results. Community involvement significantly enhances the chance of sustainability and long-term success of interventions as well. Some scholars suggest immersing oneself in the cultural community to become a more sensitive partner; others suggest participatory research models aimed at empowering and building capacity at the local level. At the foundation of different contemporary approaches, however, is an orientation toward dialogue, with

researchers and other stakeholders explicitly stating values, assumptions, and priorities to avoid a prevention focus that is not relevant or salient – or even worse, furthers inequalities or oppression.

Meaningful adaptation of prevention programs reflects the integration of cultural values at a deep structural level rather than just on a surface level (Nation et al., 2003). As noted in the previous section, prevention researchers are currently focused on finding a successful balance of meaningful adaptation with program fidelity, emphasizing the retention of core program components and an adequate strength or 'dosage' of a program across settings (Kumpfer et al., 2002). One of the key challenges in the field is to figure out the essential 'core' ingredients for a particular intervention to be successful as it is adapted across diverse cultural contexts. With this emphasis on finding the right blend of program fidelity and adaptation, it is becoming increasingly clear that program implementation in any specific context is necessarily also a process of program innovation.

Another challenge for the field is to work across levels of analysis, examining not just processes and outcomes for individual-level change, but collecting evidence of organizational and systems change. As discussed previously, preventive interventions often work to identify risk factors within communities that have high rates of poverty and/or people of color. Thus, researchers have noted the need to identify culturally relevant strengths at individual and community levels to implement relevant and valued interventions and to avoid pathologizing entire communities (Kenny and Hage, 2009). A health-promotion framework for prevention enables thinking about interventions that build on strengths within minority communities (National Black Child Development Institute, 2013) and working with majority groups to promote economic and social inclusion within and across communities (American Psychological Association, Presidential Task Force on Preventing Discrimination and Promoting Diversity, 2012). For example, new efforts to prevent interpersonal and institutional racism work across multiple levels of analysis, not just focusing on individuals and groups, but also focusing on social institutions and systems that perpetuate inequality and exclusion. They include interpersonal interventions drawing on social psychology's contact theory to prevent the formation of racist attitudes and beliefs, as well as public policy advocacy as an organizational and systems-level prevention strategy (Buhin and Vera, 2009).

Prevention and Public Policy

Earlier we cited research demonstrating the cost-effectiveness of community-based prevention programs in Pennsylvania (Jones et al., 2008). The research found that the programs generated up to $25 in savings for every dollar invested by the Commonwealth. Much of these savings came from decreased costs to the criminal justice system. Home-visiting programs, high-quality day care, mentoring programs, and parenting training programs have all been shown to reduce crime and crime-related costs to the point where the programs more than pay for themselves. Yet, in the United States there has been an immense increase in public funding for incarceration in recent decades, at the same time that funding for prevention programming has been cut.

This disconnect between the findings of prevention science and public policies is widespread and a source of frustration to many prevention scientists. The goal is not just to advocate for the adoption of specific programs. Rather, their goal is to provide broad education to policy makers regarding the benefits of prevention approaches. The importance of this work is illustrated by the Guidelines for Prevention in Psychology, adopted by the American Psychological Association. Guideline 9 specifically states that "Psychologists are encouraged to inform the deliberation of public policies that promote health and well-being when relevant prevention science findings are available" (American Psychological Association, 2012). As we hope we have illustrated in this article, a wealth of prevention science exists. Perhaps the major challenge faced by the field is to ensure that our institutions, communities, and public policies are informed by that knowledge.

Summary

In this article we reviewed the growth of prevention from a cultural value to specific areas of study across many disciplines. The future holds promise as we look to develop more systematic approaches to engaging communities to address their needs and more effectively promote policies that are both cost-effective and promote health and well-being for various groups in our communities.

Abstract

Into the twenty-first century, primate biology remains a critical area of research for understanding the evolutionary ecology of human social behavior. In this article, we briefly outline the history of primate behavioral studies within the field of physical, now biological, anthropology, discussing past uses of primatology for building hypotheses for human behavioral evolution. We then discuss changes in the theoretical approach to the study of primate behavior and their effects on the understanding of social systems. We conclude by presenting current issues in primatology as they relate to the study of human sociality and behavioral evolution.

Introduction

Into the twenty-first century, primate biology remains a critical area of research for understanding the evolutionary ecology of human social behavior. The modern anthropological subfield of primatology began with anatomical comparisons of nonhuman primates to reconstruct the morphological evolution of humans, and interest in the behavioral similarities between human and nonhuman primates can be traced to Huxley's (1863) assertion of a phylogenetic relationship between humans and African apes. Since their inception, primate studies have been incorporated into diverse fields of inquiry beyond anthropology that include biology, ecology, and psychology. Physical anthropologists were interested principally in the degree to which primates and their behavior could be utilized as a model for reconstructing the behavior and cognitive capacities of ancestral humans. Contemporary primate studies continue to inform a broad array of fields in both the human and nonhuman behavioral sciences, and this integrative approach contributes to our understanding of both human evolution and the behavior of extant humans (Washburn, 1973). In this article, we briefly outline the history of primate behavioral studies within the field of physical, now biological, anthropology, discussing past uses of primatology for building hypotheses for human behavioral evolution. We then discuss changes in the theoretical approach to the study of primate behavior and their effects on the understanding of social systems. We conclude by presenting current issues in primatology as they relate to the study of human sociality and behavioral evolution.

Early Primate Models of Ancestral Hominin Behavior

Early primate models for the behavior of ancestral humans were based on either (1) assumptions of similarity in ecological adaptation between extant savannah-living primates and ancestral humans, or (2) shared behavioral traits within the clade of African hominoids. Raymond Dart, the discoverer of the late Pliocene *Australopithecus* specimen at Taung, in South Africa, popularized the hypothesis of a saltatory shift to human bipedalism, tool use, and hunting as a result of moving from forested habitats to savannahs (Dart, 1957). Specifically, Dart drew explicit parallels to baboons as contemporary savannah dwellers that might share behavioral similarities with ancestral humans. However, subsequent, though brief, field studies of wild baboons revealed distinct differences from modern humans. Nonetheless, early descriptions of baboon sociality (DeVore and Washburn, 1963), which emphasized male dominance and aggression as important influences on social structure, were used to typify the human condition (Kinzey, 1987). The historical prejudices and methodological weaknesses that gave rise to these models have received considerable critical scrutiny (Cartmill, 1993) and, although both the conceptual approaches and practical challenges to fieldwork were anticipated (Carpenter, 1945), these early studies planted the seeds for future primate field studies by asking the following questions: (1) In what way do ecological variables shape social systems? (2) What were the relevant ecological factors that shaped early human evolution? and (3) What can extant primates tell us about human sociality and behavioral evolution?

Ecological affinities led to the baboon model, whereas phylogenetic affinities between humans and nonhuman apes prompted field studies of chimpanzees, gorillas, orangutans, and bonobos (Hamburg and McCown, 1979). Taking a comparative approach, Louis Leakey sponsored well-publicized field studies of three great ape species. Anthropologists focused most attention on the common chimpanzee because of their close anatomical, behavioral, and genetic affinities with humans (Sibley and Alquist, 1987). Behaviors observed in both humans and chimpanzees were assumed to be phylogenetically conservative and therefore likely to have been expressed in our last common ancestor. For example, tool use and manufacture; meat eating, with cooperative hunting and sharing; and the mixed savannah/woodland landscape of chimpanzees at Gombe, in Tanzania, reinforced the importance of this suite of characteristics to the evolution of modern humans (Kinzey, 1987).

However, contrary to expectation, these studies revealed that neither baboon nor chimpanzee models necessarily have strong explanatory power in reconstructing the behavior of ancestral humans. First, extant species evolved under unique selective pressures and are not satisfactory typological specimens of ancestral species. Second, there is significant intraspecific variation in the behaviors of chimpanzees and baboons, with no adequate criteria for selecting which behaviors are applicable to models of ancestral humans. Third, if behaviors common to chimpanzees and humans are assumed to be phylogenetically conservative, there are significant problems in interpreting from the fossil record morphological evidence that is not shared by either modern chimpanzees or humans (Potts, in Kinzey, 1987).

These criticisms apply to the assumptions and methods employed by these modeling approaches and not to the usefulness of primate behavioral studies per se in elucidating ancestral and current human behavior. Past mistakes have served to refine the approaches by which primate studies are conducted and applied. At the beginning of the twenty-first century, few primate studies now make explicit use of typological models. Instead, contemporary studies of primate behavior emphasize a comparative approach in which the functions of behaviors are investigated under varying ecological and social conditions. The next section presents important conceptual changes in the study of primate behavior and their influence on our understanding of human behavior.

Conceptual Shifts in Primate Behavior Studies

During the same time that primate behavior was being used to construct models of ancestral hominines, it was also an area of active interest in the zoological sciences, particularly in the subfield of behavioral ecology. Behavioral ecology investigates behavioral adaptations to varying ecological and social conditions. Although behavioral ecologists directly observe phenotypic traits and behavioral strategies, they use these observations to test falsifiable predictions generated within an evolutionary framework in which natural selection favors individuals who act in ways that increase their inclusive fitness. For example, studies testing optimal foraging theory use economic cost–benefit models to generate predictions of behavioral responses to ecological conditions that affect an individual's energy budget. Other studies, particularly those that focus on reproductive behavior such as mating and offspring care, examine an individual's decisions when situated in a particular social milieu (Krebs and Davies, 1991). This approach to the study of primate behavior is distinctly different from that which was used previously in two important ways: (1) its goal is to test and further develop general evolutionary principles for behavior rather than create models of specific extinct species, and (2) comparative outgroups can be taken from all animal taxa rather than those restricted to the primate order.

Within the field of anthropology, human behavioral ecologists applied evolutionary concepts to test economic models of the ecology of contemporary human hunter-gatherers. Human behavioral ecologists focused on contingencies that had been found to be important in nonhuman primates: predation, reproductive opportunities, and the spatiotemporal distribution and abundance of resources. However, the application of primate studies to the interpretation of human behavior encountered significant difficulties following the publication of E. O. Wilson's *Sociobiology* (1975). Criticism of early sociobiological theory is well documented and expressed two main concerns. First, the effusion of speculations about the application of sociobiological principles to human behavior was untestable and therefore unfalsifiable (Caro and Borgerhoff Mulder, 1987). The second body of criticism, which objected to sociobiological depictions of humans as inflexible executants of the interests of selfish genes, stemmed from a poorly explained differentiation between genotypic determinism and the phenotypic expression of behavioral flexibility. Suites of behaviors resulting from complex socioenvironmental conditions (e.g., rape) were incorrectly treated as simple units of evolutionary analysis (Sunday and Tobach, 1985). Disagreement about the application of sociobiological theory to the study of human behavior resulted in a division between cultural anthropologists, who emphasized human uniqueness, and those biological (formerly physical) anthropologists who studied primate behavior with an eye toward understanding that of humans. Although it is a truism that genetic makeup influences behavior, and genetic relatedness influences to whom particular behaviors may be expressed, genetic determinism has no place in behavioral ecology.

The contemporary use of primate behavior within anthropology has shifted from the use of primates as typological models of human origins to field studies and experiments that test predictions developed within a behavioral ecology framework (Rodman, 1999). Significant methodological changes have accompanied this theoretical shift. First, standard methods for the collection of quantifiable data facilitate interpretable statistical tests of predictions and comparison across primate studies (Altmann, 1974). Second, more primate species are studied, thereby providing larger and more diverse samples for comparison. Third, long-term field studies provide information on seasonal and interpopulational variability in behavior, the ontogeny of and change in relationships among individuals, and the causes and consequences of demographic processes among long-lived species. Fourth, a more diverse representation of scientists expands the field of inquiry to include aspects of social life previously assumed ancillary to social organization, particularly female reproductive strategies and the energetics of offspring care (Altmann, 1980; Hrdy, 1999). Analyses of the resulting data sets demonstrate rich intra- and interspecific variabilities in behavior and relationships that parallel the intraspecific variability observed in humans.

Current Primate Studies in Anthropology

Social Behavior

Two general principles are commonly invoked to explain group size and composition in birds and mammals. First, female reproductive success is limited primarily by the availability of ecological resources, particularly food. With whom females form groups, and the competitive regime between females

within those groups, is a function of the distribution of ecological resources in space and time (Wrangham, 1980; van Schaik, 1989). Male distribution, on the other hand, is patterned upon that of females (Andelmann, 1986). The diversity of grouping patterns observed among primates across a range of environments supports this general framework.

Whether of the scramble or contest type – a reflection of resource monopolization – competition for resources underlies this ecological model (Krebs and Davies, 1991). Competition, however, can be expressed in multiple ways. Aggression between group members certainly occurs, and individuals obtain inclusive fitness benefits by aiding kin in contests, but not all competition results in direct conflict. Unrelated individuals also engage in cooperative and affiliative behaviors, and reconciliation often occurs after conflicts (de Waal, 1983). Indeed, several benefits accrue from affiliative interactions with nonkin. First, individuals who engage in postconflict reconciliation experience more rapid reductions in stress responses than those that do not (Aureli, 1992). Second, initiating affiliative behaviors garners favor with powerful group members and develops relationships with potential future allies (de Waal, 1983). Third, males who invest in nonsexual affiliative behavior toward females obtain future matings with their 'friend' (Smuts, 1985). Peaceful interactions are essential to the social cohesion of groups and provide alternative means of exerting influence and eliciting support. Long life spans and the opportunity for repeated encounters between known individuals provide the conditions under which individuals can predicate present behavior related to anticipated future social interactions (Trivers, 1971; Byrne and Whiten, 1988).

The study of behavioral ecology in humans is likewise concerned with the tactics employed by modern humans to survive and reproduce within a particular socioecological context. Using principles developed in the field of animal behavior, human behavioral ecologists collect data from modern hunter-gatherers to test predictions derived from ecological optimization models related to food acquisition, time allocation, and habitat use (Winterhalder and Smith, 2000). Human behavioral ecologists are able to measure directly the economic results of behavioral traits thought to be important to human evolution, such as altruistic cooperation and food sharing, the intersexual division of labor, long juvenile dependency periods, and females' lengthy postreproductive life spans. The results of such studies have led to important challenges to the primacy of hunting in human history, suggesting instead that the economics of female provisioning and care of offspring provide a more parsimonious explanation for the evolution of human social systems (Hawkes et al., 1997; O'Connell et al., 1999).

Despite the general applicability of behavioral ecology models, there is strong evidence that primate studies in particular are more informative for understanding human sociality and behavioral evolution than research with other animal taxa. While studies of other taxa, particularly social mammals, serve to test theories that may be relevant to humans regarding the causes and consequences of different social systems, the complex nature of social relationships observed in nonhuman primates make them particularly useful as comparative species for understanding the function of human social relationships. In addition, the use of nonhuman primates as comparison species controls for traits more phylogenetically conservative than behavior that may influence alternative strategies (e.g., functional morphology, life history parameters, and physiology). Confining the study of behavioral ecology to humans within the field of anthropology limits the perspective from which to understand human behavior. For example, cross-cultural studies can demonstrate intraspecific variation, but they do nothing to reveal which traits or behaviors are uniquely human. Interspecific comparative studies among primates reveal the extent and degree to which certain behavioral patterns are confined to humans. Hence, primate studies both focus and expand the field of vision in the study of human behavior.

Functional Morphology

Anatomists have a rich tradition of inferring the behavior of extinct species based on fossil skeletons, and tooth morphology figures prominently in the reconstruction of hominin diets (Jolly, 1970). Interpretation of fossils is possible, however, only with studies of analogous structures and their function in extant species, but researchers must also be careful in their phylogenetic interpretations because shared skeletal morphology may not always mean shared evolutionary history (Wood and Harrison, 2011). Recently, anatomists have teamed up with primate behavioral ecologists to combine direct observations of primate feeding behavior with dental morphology. This partnership helps to refine the techniques used to determine ancestral diet and feeding patterns. For example, field studies of the feeding ecology of four sympatric Sumatran primates allowed Ungar (1996) to test whether incisor size corresponds with diet. His finding that incisor size and shape best reflect the mode of ingestion rather than diet per se resolves some conflicts in interpretations of the fossil record. Dental microwear analyses can reveal more detailed information about diet than can analysis of gross dental morphology. Recent field studies examine primate feeding behavior, measure the physical properties of foods, and cast the teeth of wild primates so as to better understand the relationship between food type, mode of ingestion, and microwear (Teaford, 1994). Similar studies are being conducted on humans (Ungar and Spencer, 1999). With further refinement of this new technique, analysis of dental microwear can play an important role in the reconstruction not only of the diet of ancestral hominines but the use of teeth for nonfeeding functions as well (Teaford, 1994).

Studies of positional behavior investigate the relationship between postcranial musculoskeletal anatomy and locomotion. The means by which wild great apes travel in their natural environments reveal the function of bone and muscle in the limbs (Fleagle, 1999), and the study of comparative anatomy between great apes and fossil hominines provides a basis for inferring locomotor behavior in hominines. This approach has shown that bipedal hominines descended from an arboreal primate that moved primarily by climbing rather than brachiating (Fleagle, 1999). Likewise, *Australopithecus*

afarensis, the hominin most likely responsible for the famous Laetoli footprints (Leakey, 1987), probably spent a good proportion of the day moving arboreally (i.e., from tree to tree) as well as bipedally (Stern and Susman, 1983). Field observations also provide clues to possible sex differences in behavior. In apes, sexual dimorphism corresponds with differential use of arboreal and terrestrial substrates for moving, with males spending more time on the ground than females (Doran, 1996). If the sexually dimorphic *A. afarensis* moved on the ground and in the trees, sex differences in substrate use may likewise have occurred.

Intelligence and Cognition

The comparative study of intelligence and cognitive abilities among nonhuman primates in the laboratory spans more than half a century (Russon et al., 1996). The discovery of tool manufacture and use in wild chimpanzees (Goodall, 1968) put to rest concerns that the development of the cognitive capacities necessary to use tools by laboratory primates was an artifact of intensive interaction with humans. Wild orangutans also manufacture and use tools with considerable complexity (Fox et al., 1999). In contrast, the proficiency with which capuchin monkeys use tools in both field and laboratory settings is significantly lower than that of great apes (Visalberghi and Trinca, 1989). Great apes have crossed the line into a domain of intelligence once postulated to be uniquely human; furthermore, the intelligence required for ape-level tool use and manufacture evolved before the orangutan–African ape split (van Schaik et al., 1996).

Tool use behavior, however, is only one demonstration of intelligence. The decision-making processes required for large-bodied apes to travel arboreally is another (Povinelli and Cant, 1995). Complexity in social interactions such as deception evinces cognitive skills as well (Byrne and Whiten, 1988). Primate studies provide empirical proof that many purported aspects of human uniqueness, such as intelligence and culture, are unique to humans only insofar as they are defined as such (Cartmill, 1990). The corpus of work in this field demonstrates that, broadly defined, intelligence has evolved by degrees rather than as a result of a single selective pressure on early hominids. Diverse levels and types of cognitive capacities in ecological and social domains for an array of primates elicit two questions about humans: (1) Is the higher intelligence demonstrated in humans an added degree of intelligence or is it a difference of kind, or both? and (2) What selected for human-level intelligence? Language, cumulative culture, and altruistic cooperation reflecting prosocial tendencies are obvious difference between humans and nonhuman primates, and they will undoubtedly figure prominently in answering these questions.

Future Directions in Research

Although most primate species live in cohesive social units with permanent male–female associations, groups also comprise individuals with interests that often differ from those of their groupmates. In addition, those interests change as individuals grow to maturity, reproduce, and then, in some species, shift into a postreproductive phase of life. Building upon earlier research, future studies are needed to investigate the complexity of factors that influence individual decisions within the context of group life, in particular, (1) the strategies that individuals employ to satisfy their reproductive interests, even when those interests conflict with other group members; and (2) reproductive decisions that incorporate not just matings or fertilizations, but offspring survival as well.

Male aggression, or the threat of aggression, toward females is observed in most species of primates including humans (Smuts, 1992; Smuts and Smuts, 1993). Some of this conflict is with current or potential mating partners. However, significant variation in rates of sexual aggression occurs between and within species (Arnqvist and Rowe, 2005). For example, woolly spider monkey females copulate without aggression from their mates or other males, while male sexual aggression in rhesus macaques occurs frequently. In baboons, particular males develop 'friendships' with females while others do not (Smuts and Smuts, 1993). There is even variation in individual males: some human males with pair-bonded mates force copulations with other females, and some pair-bonded males alternately exhibit affiliative and aggressive behavior toward their mates (Ellis, 1989). Despite the seemingly widespread occurrence among primate species, however, extreme forms of direct sexual aggression in the form of forced copulations are uncommon in primates other than humans and orangutans. Some hypotheses to explain this striking contrast have been proposed and deserve further exploration.

What is the function of male sexual aggression? Under what conditions does it occur? Feminist scholars and biological and social scientists have long recognized that conflict between female and male reproductive interests influence individual behavior and shape the social systems in which individuals live (Hrdy, 1977; MacKinnon, 1989; Arnqvist and Rowe, 2005). Theoretical treatments of intersexual mating conflict in human and nonhuman primates provide a basis for predicting the conditions under which male sexual aggression, and conversely female counterstrategies to thwart males, occur (Smuts, 1992; Smuts and Smuts, 1993). Recent studies provide some preliminary basis for comparison (Smuts and Smuts, 1993), but to strengthen the comparative method, more studies conducted across a greater spectrum of primates are necessary. Of particular importance is quantifying the costs of sexual coercion, such as reduced foraging efficiency, in addition to infant or female mortality. New noninvasive hormonal assay techniques for field-collected samples are starting to be used (Whitten et al., 1998) and will allow researchers to measure endocrine response by females who are subjected to male sexual aggression. Using these techniques, research can reveal the degree to which male aggression produces physiological effects that may negatively impact female fecundity.

Relatively little is understood regarding why females resist mating with some males but not others. Equally little is known about female tactics to circumvent male attempts to restrict female reproductive choice. More studies are needed to determine the degree to which females select mates based on variations in genetic quality or resource-holding potential among males (direct mate choice) or whether other factors, including

male aggression, sufficiently constrain females and lead to facultative, or indirect, female mate choice (Gowaty, 1992; Wiley and Poston, 1996). Whether for genetic quality, direct benefits, or constraints placed by males, with whom a female mates has an important reproductive outcome. Females are therefore predicted to exercise tactics, including sperm selection, that optimize their abilities to retain control over reproductive choice and the timing of reproduction. Techniques for genetic analysis using noninvasive sampling methods have been developed (Borries et al., 1999) and will in the future facilitate evaluation of the success of both male and female reproductive strategies.

Variability in male reproductive decisions is also important. In contrast to the previously pervasive view within evolutionary studies and behavioral ecology, a recent shift recognizes that the acquisition of multiple mates is not the sole factor motivating male reproductive decisions. Whether they are excluded by other males, fail to attract mates, or are constrained by the need to allocate time to nonmating activities, male primates are limited in the number of females with whom they can mate and produce viable young. Males, therefore, optimize reproductive effort within existing constraints. Limitations on male mating opportunities have traditionally been viewed in terms of intrasexual competition and mating aggression toward females, but this is not always the case. Male choosiness for mates is likely to be one important tactic in species that have long periods of infant and juvenile dependency (Altmann, 1997). Differences in female fertility, for example, may guide males away from young females as mates. Furthermore, conception and birth are merely the first steps to reproductive success; offspring must survive into adulthood to reproduce because reproductive success is most accurately measured in the second generation (Clutton-Brock, 1988). Offspring survival is critically dependent on maternal competence, including mothers' abilities to obtain access to resources necessary to rear young. Males are, therefore, expected to prefer those proven females who are older, higher ranking, and reproductively experienced (Altmann, 1997).

Females with insufficient resources to rear young may abandon current offspring to invest in future reproductive opportunities. Alternatively, to meet the demands of rearing offspring, mothers in some species share the task of offspring care. Fathers sometimes significantly assist females, and the need for paternal care constrains male promiscuity as it does in many species of birds (Clutton-Brock, 1991). Likewise, related or unrelated individuals sometimes assist mothers. Related individuals gain inclusive fitness benefits resulting from the survival of grandchildren, sisters, and cousins, while both related and unrelated individuals may gain needed experience necessary for the survival of their own future offspring (Hrdy, 1999). Long juvenile dependency and the need for assistance in rearing offspring play important roles in the lives of extant hunter-gatherers, and it figures prominently in models of human social evolution (O'Connell et al., 1999). The function of extended juvenile dependency, how mothers meet the demands of extensive infant care, and the consequences for reproductive success are among the most fascinating questions of human and nonhuman primate life histories. Yet because primate life spans are so long, these questions are also among the hardest to study. As data from uninterrupted long-term field studies become available, questions concerning the fitness advantages of variations in parental and alloparental care will be addressed.

Primate Groups and Their Correlates

Pascal Gagneux, University of California San Diego, La Jolla, CA, USA

Abstract

Most primates are highly social and live in groups ranging from small reproductive units to large troops counting hundreds of individuals. Spatial and temporal distribution of food resources, competition with other species, and threat of predation are important determinants of primate group size. Many female primates and their dependent offspring forage largely independently of males, and most primate groups are female bonded. Furthermore, mating and breeding occur in a large variety of ways and may include individuals from outside existing groups. Like their closest living relatives, the chimpanzees and bonobos, humans live in multimale, multifemale groups. However, humans differ from all other primates by commonly forming strong pair bonds within such groups. Cultural norms for group affiliation and mating patterns can shape the genetic structure of human populations.

The Diversity of Primates, Their Social Organization, and Their Mating Systems

Primates include over 300 species of prosimians, monkeys, apes, and humans. These range in size from mouse-sized prosimians and pigmy marmosets weighing less than 100 g to orangutans and gorillas where males weigh over 200 kg. Most primates are tree dwelling, but some, such as gorillas and baboons, are mostly terrestrial. While some of the prosimians (a group of relatively 'primitive' primates including galagos, pottos, lorises, and lemurs) are nocturnal and mostly solitary, the vast majority of primates are diurnal and extremely social. In fact, sociality and sexuality are key primate adaptations. Biologists use the term 'mating system' to describe the patterns of behavior related to mate choice, reproduction, and dispersal. Such mating systems are intimately linked to the social system the animals live in, but they are not one and the same. Mating partners include, but need not be restricted to, social partners. A key characteristic of females in many primate species is their monthly ovulation. Breeding seasons do exist in some primate species, but overall, periods of female fertility are more frequent in primates than in most other large mammals. Accordingly, sexual behavior is frequent, and it has acquired functions in addition to reproduction.

Primate mating systems represent a wide spectrum ranging from polyandry, where a single female mates with several males (South American tamarins); to monogamous or serially monogamous pairs (owl monkeys and gibbons); to multimale, multifemale groups (chimpanzees, spider monkeys, red colobus monkeys, and many baboons); to single-male, multifemale groups, where the male has exclusive reproductive access to multiple females during his tenure (gorillas and mandrills). Single-male groups can experience temporal visits by groups of bachelor males (guenons); conversely, solitary males and females can temporarily gather when resources are plenty (orangutans).

Size differences between males and females (sexual dimorphism) seem to correlate with the degree to which males of a given species are polygynous (i.e., compete for reproductive access to females). Males and females of the monogamous gibbons or owl monkey (*Aotus*) are the same size, but males of the polygamous gorillas and mandrills can weigh more than twice as much as conspecific females. Male primates are often in intense competition for access to resources and fertile females. In some primates, including our closest living relatives, the chimpanzees, males collaborate in defending resources (they are strongly territorial) and females.

Primate mating systems are far more flexible and dynamic than previously thought. Changes in resource distribution or social changes can cause animals to alter the ways in which they find and choose mating partners. The same species may show different mating systems in different locations or at different times in the same location (Dunbar, 1988; Dixson, 2012).

Reproductive Strategies of Male and Female Primates

Sexual reproduction refers to the process by which male and female germ cells (sperm and egg) fuse and produce individuals with unique (and ephemeral) genetic combinations. The (haploid) germ cells carry half of the reshuffled chromosomes that the parents inherited from the grandparents. Female germ cells (ova) are large, costly to produce, and limited in number (one per month for three or four decades at most). In contrast, male germ cells (sperm) are tiny, much cheaper to produce, and are produced in huge numbers (hundreds of millions per day) throughout life by mature males. In animals with internal fertilization and gestation, this discrepancy in reproductive investment is exaggerated as females invest substantial resources into the developing fetus during gestation.

Female mammals bear an even more disproportionate cost of reproduction because of lactation, the physiological cost of which is higher than that of gestation itself. Prolonged parental care in primates adds to that burden as it is mostly provided by mothers. Male investment may end with successful insemination, after which males can look for further mates. The average number of offspring born to male and female of a given primate species is roughly the same, but the variance is much higher in males, where some highly successful males sire large numbers of offspring and many others none at all.

Biologists have repeatedly pointed at the imbalance between male and female reproductive costs to explain why males have a natural tendency to be promiscuous while females tend to be 'coy' and choosier (Hrdy and Williams,

1983). This caricature of male emphasis on quantity and female emphasis on quality is in part responsible for the fact that students of animal behavior have long overlooked the importance of female choice and multiple paternity (Lackman-Ancrenaz et al., 1992). Females, much rather than just being passive 'resources' for which males compete, are pursuing their own reproductive interests very actively, often within the constraints of male physical dominance and female–female competition. Their strategies are often less conspicuous and may involve long-term patterns, which explains why they have so often been overlooked.

Male primates can undoubtedly increase their reproductive success by maximizing the number of matings with fertile females. In multimale groups, this can occur by (mostly) physical dominance of one male over others. Subordinate males in such groups can achieve reproduction utilizing different approaches, such as 'consortships' in chimpanzees, where a male and female temporarily leave the social group.

There may be strong advantages to multiple matings for females as well. Primates have long periods of development, and infants are very dependent on parental assistance. Parental care, mostly by mothers but in many cases also involving allo-mothering by other group members including males, is crucial to primate reproduction. The tamarins, small primates of the Amazon forest, even have cooperative paternal care for the twins born to the female. The offspring of many primate species benefit from the protection and care provided by males with whom their mothers associate. Infant baboons and infant gibbons are often carried by males. In the monogamous owl monkeys, the infants are carried mostly by the male, and chimpanzee males are known to adopt orphaned male infants. Wherever male help is needed with the rearing of offspring, and there are several males present in the group, incertitude of paternity can cause males to assist offspring that they did not sire, resulting in a strong motivation for females to mate with many different males. On the other hand, too much incertitude about paternity is potentially dangerous, as males can be a threat to offspring that they perceive as not their own. Infanticide by males is well documented in several primate species, including gorillas and chimpanzees.

Genetic Consequences of Mating Patterns

The unique genetic identity of each individual can be directly characterized by genetic methods based on the identification of highly variable genetic loci (stretches of DNA located on particular chromosomes). Sampling of wild individuals can be based on small samples of tissue, blood, hair, or feces. These can be collected noninvasively or with minimum discomfort to the animals using small biopsy darts. There is much information from dozens of long-term research sites about the genetic composition of social groups, paternity within the group, and genetic differentiation between males and females and between different social groups and geographically distinct populations (Di Fiore, 2003).

A dozen or so highly variable loci can be amplified from samples using the polymerase chain reaction technique and will provide a unique genotype for each individual, defined by the combination of two genetic variants (alleles) found at each locus. The most commonly used type of loci are simple sequence repeats (also called simple tandem repeats or microsatellites), short stretches of repeated sequence motifs that have a very high mutation rate and thus exist in a number of states (alleles with a distinct number of repeats) within each population. In addition, short sequence reads from the clonally inherited mitochondrial DNA and Y chromosomes can help determine the maternal and paternal ancestry of each individual. These pieces of DNA are inherited without recombination and only through one parent, and can thus be used to measure male- or female-mediated gene flow.

Studies of genotypes in a large number of species of wild primate populations have yielded genetic evidence for several aspects of reproductive and social behavior. Female-bonded baboons show higher relatedness among females (these share more genetic variants when compared to the general population) but not males, which are known to disperse from their natal groups after puberty (Altmann et al., 1996). Studies of gorilla groups have confirmed that a single resident male, and sometimes also his brother, sire most of the offspring with the group's females (Nsubuga et al., 2008). Male orangutans have been found to employ their two different mating strategies with success: both large, flanged males chosen by females as well as small, nonflanged males that coercively mate with females sire offspring (Goossens et al., 2006). In many species with multiple males and females, higher male rank correlates with higher reproductive success. This is true for chimpanzees as well, but alternative mating strategies by lower ranking males combined with female preferences contribute to substantial reproductive success for lower ranking males as well (Wroblewski et al., 2009).

A surprising finding is that males from the same chimpanzee communities are not more closely related than are females, despite the fact that chimpanzees are mostly patrilocal (females disperse around sexual maturity and males remain in their native groups). A possible explanation for this finding is that the rate of extragroup paternity might be elevated enough (6–10%) to introduce sufficient male gene flow between social groups (Schubert et al., 2011). This indicates that social units and reproductive units need not be completely identical.

Sex as a Social Tool

In bonobos, apes known for their frequent sexual interactions, sex is directly used to reduce tension in the group and is often exchanged for food. Chimpanzee females exchange sex for meat that is usually controlled by males, which do most of the hunting and use meat as a social currency mostly among themselves. A female chimpanzee will copulate more than 6000 times with a very large number of males (10–30) while she can maximally produce only six surviving offspring. Similarly, the high frequency of same-sex sexual contact in bonobos plays important social roles. In fact, bonobos appear to be the one species of primates where frequent female–female sex facilitates the existence of strong female alliances, alliances strong enough to keep male aggression and dominance in check.

Advertised Ovulation in Multimale Groups

Females in many species with multimale groups exhibit conspicuous pink swellings of their genital area during several days around the time of their ovulation. These swellings are known as estrous swellings, and they represent a formidable 'tool' of female primates. Different species of primates have independently evolved these signals, including gelada baboons, where the swelling is on the female's chest rather than around her rear end.

A female with a swelling becomes the focus of attention of all males in the group. Her social status increases, and males will compete for access to her. Several females can have estrous swellings at the same time, thus making it virtually impossible for any given male to monopolize access to all of them. Estrous swellings appear to play an important role for species in which females disperse and join new social groups after they become sexually mature. Swellings are a kind of 'social passport' that greatly facilitates a female's acceptance by unfamiliar males.

There is evidence for certain amounts of disconnect between the advertising of fertility and the actual time of ovulation. Such a disconnect could work to the advantage of the female because she could escape the controlling efforts of certain males and exert a freer choice of paternity for her offspring. The topic of 'concealed ovulation' takes on considerable importance as many scientists have suggested that humans have attained a stage of perfectly concealed ovulation (concealed even from a large proportion of women themselves). To what degree the inability of human males to detect the moment of peak fertility in women has played a role in leading to the pair bonding in our species is a much-debated issue.

Advertised Male Quality

Female criteria for choosing their mates remain poorly understood. In gelada baboons, male chest coloration is directly proportional to social status (Bergman et al., 2009). Females can certainly learn about future social partners through their year-long interactions with males, but for detecting 'good genes' they must rely on indirect signs such as body symmetry and relative absence of disease and parasites.

Determinants of Sociality in Primates

The distribution of resources and the presence of predators play key roles for the distribution of individuals across space. When resources are clumped, groups of animals can live around a particular cluster of resources and defend a certain territory. Such groups can form cohesive social units. When resources are few and very dispersed, no single cluster of resources can be defended even by large groups of animals. Such environments tend to harbor animals living in much smaller groups or as dispersed individuals. Even highly social populations of chimpanzees are known to scatter into much smaller subgroups during periods of low food abundance. The solitary orangutans, on the other hand, can gather in large numbers during periods of plenty (mast fruiting).

There are many good reasons for living socially. More eyes can see better, and more ears can hear better. Living socially facilitates the search for food and the detection of predators. Another advantage is the phenomenon of the 'selfish herd,' where the presence of other individuals spreads the risk of predation as any of the other group members is as likely to be preyed upon as oneself. Also, cooperation in antipredator defense is possible only in groups. Obviously, social life facilitates finding mates, even if it will increase the competition for them. Animals in groups can cooperate in defending resources against competitors. Such cooperative resource defense, when done by males, may have the added benefit of attracting females to the group, which may represent unwelcome competition to the females already resident in the group. Finally, the presence of individuals possessing different capabilities (such as hunting, raiding beehives, and remembering the time and place certain foods can be harvested) in a group will benefit all group members.

Unique individual experience and history shape large-brained long-lived organisms such as primates. The mating strategies within a social group can vary dramatically between individuals. Some males in multimale groups, for example, may not show any ambition with respect to the dominance hierarchy. They spend their whole life as subordinate males. Their friendship with certain females in the group may in the end translate into numerous offspring. Certain females may be much more successful at forming social bonds with dominant males. Sheer force can allow a male to ascend in the dominance hierarchy, but the majority of individuals in his group may not follow him. The cognitive capacities of primates appear to have coevolved with their tendency for sociality. Long-lasting relationships with many group members require good memory and benefit greatly from social intelligence.

Costs of Living Socially

There are multiple costs to sociality. Competition between males can create social instability and conflict. Such conflict is often violent and can lead to harm to bystanders, or even infanticide by males that hope to remove the offspring of competitors and gain rapid access to fertile females (the loss of an infant causes lactating females to resume ovulatory cycles).

Competition between females also occurs, for access to males, access that may lead to support (shared resources) and male protection during social conflicts. Competition between females may be the factor that precludes the formation of strong female coalitions against males in many species.

Infanticide perpetuated by females has been observed in some wild primate groups and may represent the darkest side of female–female competition for resources. The study of female dominance hierarchies in natural primate populations is still in its infancy. Such hierarchies tend to be more subtle; nevertheless, female social rank can play an important role for reproductive success and change the way females invest in sons or daughters.

A definite cost of living socially is that it can include high levels of social stress. Such stress derives from harassment by other group members (Sapolsky, 2005). Other costs of living as a social group include higher risks of infection by pathogens

and parasites and elevated risk of being detected by predators due to the noise and vocalizations associated with social interactions.

Most Primate Groups Are Female Bonded

In most primates, females and their female relatives remain in their native groups while most males disperse to other groups when they reach sexual maturity. Some notable exceptions to female residence are found in colobus and spider monkeys and in our closest living relatives, chimpanzees and bonobos, where females disperse upon reaching sexual maturity and males remain in their natal communities.

The driving force behind dispersal is thought to be inbreeding avoidance and/or competition with animals of the same sex (Moore and Rauf, 1984). Sexual mimicry in white-cheeked gibbons where adolescent females look like males and in red colobus where young males have pseudoswellings indicates that same-sex competition is important in those species.

The mechanisms underlying inbreeding avoidance are poorly understood. Whether primates are able to recognize their paternal kin by features inherited from the father, or whether they simply avoid mating with individuals from the same age cohort, is still unclear (Alberts, 1999). In humans, close proximity at an early age seems to be the crucial mechanism that triggers avoidance as sexual partners.

Do Males Follow Female Spacing?

The way females deploy themselves across time and space tends to determine how males can space themselves around females. Only if the ecosystem is capable of feeding a large number of females with enough tolerance for each other can males attempt to control such groups. A single male can control a harem, or a group of males can cooperate in female and territory defense and share the reproductive access to females. All multifemale groups create the potential for female–female competition over access to resources, and access to males and the support these may provide.

Competition between potential mates may create the opportunity to enhance the visibility of positive traits or weaknesses. Because competition involves stress and stress is known to impact an animal's immune system, competition can exaggerate the visible differences in male quality.

If female choice incites increased male competition, then female choice may indirectly lead to an increased size difference between males and females. Because strong and assertive males can be more successful at guarding resources that they share with females, females may favor the evolution of such males. Females need male protection from the unwanted attention of other males, in the extreme case even forced copulation, as well as against the threat of male infanticide; both are part of male mating strategy in many primate species (Smuts, 1993). Strong and protective males, by the same token, will be more successful at restricting the independence of females. Permanent male vigilance and mate guarding of a single female are likely to strongly reduce a male's capacity to pursue other females, and thus represent one of the ways pair bonding could come about.

The Benefit of Multiple Paternity to Females

Mating with multiple males can be advantageous for a female in various ways. As mentioned in this article, confusing the paternity of her offspring can effectively protect them from male infanticide. The female may gain support from her mating partners, both social support during conflicts with other group members and material support in the form of shared resources.

More recently, the possibility of a genetic benefit has been proposed, and some evidence is starting to accumulate (Zeh and Zeh, 1996, 1997). Because the primate fetus develops inside the mother, the female and the fetus need to achieve a type of 'immunological détente.' That is, the fetus must not be rejected by the mother's powerful immune system, but at the same time, the demands of the fetus must be kept in check, not allowing it to exact too high a toll on maternal resources.

Multiple paternity will produce more diverse offspring. Such diversity may have much to do with defense against disease. The vertebrate immune system is an immensely sophisticated and very costly system that allows long-lived organisms such as primates to survive in a world in which very short-lived, rapidly evolving parasites and pathogens (ranging from worms and protozoa to bacteria and viruses) are a constant threat. The immune system relies on genetic variation that is present in all populations as well as such generated anew in each individual in order to produce a flexible repertoire of molecular probes (antibodies and T-cell receptors), which detect telltale molecules of specific intruding pathogens. It seems critical that each fetus inherits genes coding for two rather different immunological 'toolkits' in order for the offspring to be well equipped for its countless future encounters with pathogens. Conceiving offspring with different fathers would allow females to produce sets of offspring with more variation in their immune repertoires, strongly reducing the risk of losing all or most offspring to the same disease. The same obviously applies to males as well.

Furthermore, paternal and maternal genes have to work in harmony in order to produce healthy offspring. Some combinations may simply fail to work, and yet others may work but put the offspring at a disadvantage from the start. The detection of embryos with strongly limited immune repertoires (i.e., two almost identical sets of multihistocompatibility complex (MHC) alleles, also called HLA in humans) inherited from both parents can cause spontaneous abortions in many mammal species, including our own. Because of the importance of compatibility between genomes, the most promising genes for each female are found in different males. Finally, multiple paternity may allow females to reduce inbreeding where females cannot recognize close kin.

The Cost of Multiple Paternity for Females

The immune challenges to the mother are increased with each additional pregnancy by another father. Each new father

confronts the female's immune system with a new set of foreign molecules. Data on pregnancy-associated hypertension (preeclampsia, a disease unique to humans) indicate that the risk for this immune-mediated, potentially fatal imbalance in maternal immune tolerance of the fetus is higher if the pregnancy is from another male than the previous one. A further cost to multiple paternity is sexually transmitted infections. The risk of infection is proportional to the number of different mating partners. The cost of infection ranges from a short disease episode to abortion, congenital malformation of the offspring, and permanent sterility.

Molecules and Behavior

Ova and sperm engage in intense molecular dialogue, a process that is important for creating reproductive barriers between species but that is also suspected to involve an additional level of (postmating) female choice. Female primates are known to produce a large quantity of antibodies against sperm in their genital tracts, and they also unleash huge numbers of immune cells after mating. These processes strongly favor diversity in paternity, as the antibodies would be formed against the sperm of the 'usual' mating partner, leaving sperm from unknown males at an advantage.

The role of chemoreception (pheromones) in regulating some primate behavior remains very poorly understood. The fact that primates may be able to smell important immune molecules (MHC) points toward the potentially important roles of such molecules and their detection in mate choice and sexual behavior (Wedekind and Füri, 1997). Recent genetic studies support the notion that MHC variants underlie mate choice in some human populations (Chaix et al., 2008).

Postmating Female Choice and Sperm Competition

Certain sperm may be more likely to be taken up by the egg as they approach it. Such cryptic female choice would represent a choice of individual sperm, possibly based on the genes carried by that sperm and expressed on its surface. Certain genes of crucial importance in early embryonic development are expressed on the surface of sperm.

Males can compete for fertilization of females via a process called 'sperm competition.' When females mate with many males within a short period of time, the sperm of different males will be available for fertilizing her egg. This exerts pressure on males to produce larger quantities of sperm in order to outcompete other males. In chimpanzees and bonobos, where multiple mating with many males gives rise to strong sperm competition, males have conspicuously large testicles and produce large amounts of sperm (several billion per ejaculation versus ~200 million in humans). They even produce 'copulatory plugs,' a gelatinous mass formed by seminal fluid that blocks the cervix. In gorillas, in contrast, where silverback males face very little competition in their groups, males have very small testicles and inseminate females with rather modest numbers of sperm. Gorillas and humans alike do not form copulatory plugs.

Genomic Conflicts

Because different males can sire subsequent offspring, a conflict of interest can arise between the paternal and the maternal genes. A female will spread her total reproductive efforts across all her subsequent offspring. Males are likely to have sired offspring with other females and thus are spreading their reproductive effort across several females. The larger the contrast between the number of mating partners between males and females, the more acute this conflict becomes. Paternal genes in the embryo are likely to cause each embryo to be overdemanding from the point of view of the mother. Such paternal genes will increase the male's reproductive success at a detriment to each female, who will have invested too much in that particular offspring, as opposed to evening out her investment across all her pregnancies.

It is this conflict that seems to be at the root of a phenomenon called genomic imprinting. Genomic imprinting occurs when, between the two variants of each gene present in the embryo (the paternal and maternal alleles), only one of the two is expressed. Often, only the allele inherited from the mother is expressed, while the paternal allele appears silenced. Imprinting may have several functions, but one of them may be female control of overdemanding genes from the father (Mochizuki et al., 1996; Spencer et al., 1998; Crespi, 2010).

Factors Determining Primate Mating Systems

Primate mating systems represent the outcome of a delicate balance between various constantly changing forces. These include (1) ecological factors such as the distribution of resources and pressure by predators; (2) female foraging and mating strategies, including the need to find multiple fathers of high genetic quality and good genetic compatibility, and one or more supportive social partners; (3) male mating strategies that may entail access to the largest number of fertile females, often in severe competition with other males; and (4) the need for parental care of infants and juveniles.

Compromises between male and female strategies seem to occur at every level, from gene expression to behavior. The existence of lifelong friendships between adult primates of both sexes introduces an additional dimension, that of emotional attachment and trust, between individuals.

Reflections on Human Groups and Families

The origin of the human family has long fascinated biologists and philosophers and continues to do so. Humans live in the largest groups of all primates yet primarily live in pair bonds.

Humans are unusual in forming pair bonds within larger groups of multiple males and females. Anthropological data suggest that less than a quarter of traditional human societies were traditionally monogamous, with the vast majority having mild or widespread polygyny (Murdock and White, 1969; White et al., 1988). Most foraging societies have some polygyny, but the vast majority of men are monogamous across these societies (Marlowe, 2003).

With the development of agriculture and the possibility of amassing surplus resources, polygyny became more feasible for rich and powerful males. More food also meant more humans and larger social groups. Large social groups with either monogamous pairs or polygynous units with a single male provide settings in which females can mate with males other than their predominant social partner or husband. Studies of extrapair paternity in humans are difficult to carry out and have yielded very different estimates. Some societies, such as the traditional Kalahari Desert foragers the !Kung, have been shown to have a extrapair paternity rate of 2%. For others, such as the natural fertility populations such as the Himba of Namibia, the extrapair paternity rate is 17% (Scelza, 2011). Modern Western societies can have relatively high levels of spousal infidelity, but many of these societies show very moderate rates of extrapair paternity of around 2% (Anderson, 2006).

Pair bonding appears to be an important characteristic of most human societies, and it has been argued that it was a key phenomenon in the evolution of our species (Chapais, 2008). Only prolonged pair bonding can lead to true biparentality and father–offspring recognition, which in turn would make possible the establishment of kinship networks that extend across social groups.

How old is this phenomenon? Some paleontologists have suggested that the relative lack of sexual dimorphism in possibly ancestral hominids such as the 4.5-million-year-old *Ardipithecus ramidus* strongly indicates monogamous behavior and pair bonding (Lovejoy, 2009). Others put the origin of pair bonding in the lineage leading to modern humans only at a much later time point, with the origin of the genus *Homo* and possibly the use of fire and development of cooking about 2 million years ago (Wrangham et al., 1999).

In humans, pair bonding can result from mutual infatuation and love, but in many societies, spouses are chosen by the parents and arranged marriages are important tools for forming alliances and managing wealth. Humans are the only species that have marriage ceremonies. Not all societies share these, but most have rituals that celebrate the union of a new husband and wife. These rituals often involve the participation of both families, local elders, and/or priests, and included gift giving for the newlyweds. In addition to biological incest avoidance, most human societies have strict rules against incest. The degree of relatedness considered to form incest varies strongly between societies. Many traditional societies actively encourage marriage between cousins or between uncles and nieces. Such cultural practices leave recognizable patterns in the genomes of humans in those societies, such as much larger segments of the genome without recombination than in more outbred populations (homozygosity by descent; Leutenegger et al., 2011).

Despite the fact that most traditional human societies tolerated or even encouraged polygamy, most Western societies have outlawed polygamy. In the past, exceptionally powerful male individuals such as Genghis Khan were able to produce offspring in thousands, effectively leaving genetic imprints on entire populations that can now be detected by genetic methods (such as strong biases in Y-chromosome frequencies; Zerjal et al. 2003). It has recently been suggested that the rapid spread of the monogamous norm across modern societies, most of which banned polygamy in the twentieth century, might have been facilitated by cultural evolution involving competition between monogamous and polygynous societies (Henrich et al., 2012).

More recently, human families have taken on yet other forms. High divorce and remarriage rates in Western societies bring with them the existence of many families with stepparents. There is some evidence that growing up with a stepparent can be dangerous for children due to the much higher risks of abuse perpetrated mostly by stepfathers (Daly and Wilson, 1985).

In some Western societies, same-sex couples can form legally recognized unions. These couples can adopt children or have children with the help of assisted reproduction. There is now a generation of children growing up with two fathers or two mothers.

Among heterosexual families in the industrialized world, more and more couples resort to assisted reproductive technologies due to problems with fertility. In the United States, 1–2% of all babies born are conceived via assisted reproductive technologies. These technologies can include donor sperm from a man other than the husband, donor eggs and surrogate motherhood, or even a third genetic parent in the case of nuclear transfer of an egg nucleus into the egg of a younger woman (where the mitochondria are from a different woman than the chromosomes).

Some sperm donors have achieved reproductive success of well over 100 offspring. There are attempts at limiting such numbers, and several countries have set limits to the number of offspring per donor to ranges of 2–25.

Surrogate mothers often are not the donors of the eggs, meaning that this modern method of reproduction includes a woman gestating a child with whom she is not related at all, often for financial gain. Finally, the delay in reproduction observed in many industrial societies' amounts to a large-scale genetic experiment, as it is becoming clear that the mutational load increases with parental age. Whole genome sequencing of family trios reveals that fathers, who contribute most mutations to the offspring, pass on one additional mutation with every year that they delay fatherhood (Kong et al., 2012).

Future Directions

The genetics of mating behavior are still very limited. The future will surely bring more insight into the biological basis for species-specific propensities toward one mating system or the other. Exciting findings in the regulatory region of the mammalian vasopressin receptor have been interpreted as directly causing monogamous behavior in mammals (Hammock and Young, 2005). Phylogenetic and genomic comparison of this region across a large number of rodents, however, indicates that mammalian monogamy is not controlled by a single gene (Fink et al., 2006; see also Young et al., 1999). The rapid spread of the human monogamous norm is a clear indication that social and cultural forces can rapidly mold the predominant mating system in our species. Not only is understanding primate mating systems essential if one wants to understand human evolution, but also, as many primates are currently facing extinction, such an

understanding is also crucial for conservation efforts of nonhuman primate species, in the wild and in captivity.

Abstract

Primates, an order of mammals containing some 400 extant and 500 fossil species, document a striking adaptive radiation. Extant species fall into five geographically restricted 'natural groups,' each with a distinct ancestor: lemurs, lorises, and bushbabies, tarsiers, New World monkeys, and Old World monkeys and apes. Tree-shrews, once included in Primates, are now allocated to the order Scandentia. With tree-shrews excluded, primates share many features distinguishing them from other mammals and reflecting adaptations in their common ancestor. Those features generally reflect adaptation for arboreal activity in tropical or subtropical forests. Current evidence indicate that primates may have diverged from other mammals in the Late Cretaceous.

Primates, one of 18 extant orders of placental mammals, are of special interest because they include the human species (*Homo sapiens*). Tree-shrews, generally included in Primates for some 60 years, now are widely thought to be only distantly related to primates and are accordingly allocated to their own order Scandentia. Even after excluding tree-shrews, almost 400 living primate species can now be recognized (updated from Groves, 2005), partly due to discovery of entirely new species but mainly because new information, especially evidence from chromosomal and DNA analysis, has led to subdivision of existing species. This is a dramatic increase over the 150 species listed in a leading handbook in the 1960s (Napier and Napier, 1967). The order Primates also includes more than 500 fossil species (also continually increasing as more discoveries are made), documenting the evolution of this order of mammals.

The evolutionary history of primates is a striking example of adaptive radiation, in which descendants from an original common ancestor with a particular set of features diverged and adapted to occupy different geographic areas and ecological niches. Following the advent of Darwinian evolutionary theory, this adaptive radiation was at first reconstructed almost entirely on the basis of morphological (anatomical) features. But over the years, the comparative framework gradually has expanded to include physiological, behavioral, ecological, chromosomal, and molecular evidence.

Living Primates

The logical starting point for reconstruction of primate evolution is the array of extant species. This is partly because recognition of the group began with the study of living representatives and partly because many important features (notably chromosomal and molecular characters) are not fossilized. Known fossil relatives of living primates can be included as a second step in the overall framework, and they bring with them the unique benefit of an accompanying geological time scale. Later integration of fossil species in a preliminary phylogenetic tree based on extant forms also permits use of paleontological evidence to test its validity.

Extant nonhuman primates can be divided into five 'natural groups,' each with a restricted geographic range (**Figure 1**). As geographic isolation plays a fundamental part in evolutionary divergence, these groups are inherently likely to reflect basic subdivisions within the primate tree. Indeed, they are immediately recognizable in all widely accepted phylogenetic reconstructions and classifications. The first natural group contains the Madagascar lemurs (infraorder Lemuriformes). These are the only primates present on that island, and they bear witness to a substantial local radiation (Tattersall, 1982). More than 60 extant species can now be recognized and the modern array also includes at least 17 subfossil species that died out over the past few millennia, following the first human colonization of Madagascar. The second group contains the lorises and the bushbabies (infraorder Lorisiformes). They are distributed widely in Africa, South Asia, and Southeast Asia, but the total number of species (about 28) is markedly smaller than for lemurs and represents a more limited radiation. An even smaller radiation is evident with the third group, containing about a dozen closely related tarsier species inhabiting the Southeast Asian archipelago (infraorder Tarsiiformes). The fourth group contains the monkeys of South and Central America (infraorder Platyrrhini), which are the only primates now present in the New World. This is a relatively large group of some 128 species, divided into claw-bearing marmosets and tamarins (family Callitrichidae) and true monkeys (family Cebidae). As with the lemurs of Madagascar, this once again documents a major local radiation (Kinzey, 1997). The fifth group, containing the Old World monkeys and apes of Africa, South Asia, and Southeast Asia (infraorder Catarrhini) is the largest, with approximately 132 species. In fact, humans also belong to this group, but expanded far beyond this original geological range after the genus *Homo* emerged. Within this fifth group, which is most directly relevant to human evolution, there is a clear division between Old World monkeys (superfamily Cercopithecoidea) and apes and humans (superfamily Hominoidea), although the two subgroups overlap extensively in geographic distribution.

The first three natural groups of primates (lemurs, lorises, bushbabies, and tarsiers) have remained relatively primitive and have been labeled collectively prosimians (literally meaning 'before the monkeys'). They are comparatively small (modal body weight approximately 500 g) and the majority of species are nocturnal. Diurnal species (certain relatively large-bodied members of the families Lemuridae and Indridae) are

Figure 1 Geographic distribution of living nonhuman primates (excluding tree-shrews). Shaded areas indicate the approximate ranges of the five natural groups, with the exception of the loris group (which occupies most but not all of the range occupied by Old World monkeys and apes).

few in number and occur only among the lemurs. In fact, some lemurids (species of *Eulemur* and *Hapalemur*) show a highly unusual mixture of nocturnal and diurnal activity that has been termed 'cathemeral activity' (Tattersall, 1988). This is just one example of the great diversity of unusual adaptations found among the lemurs of Madagascar.

Members of the fourth and fifth natural groups of primates (the higher primates: monkeys, apes, and humans) contrast with the prosimians in sharing a distinctive set of advanced features in their teeth, jaws, brain, and reproductive system, and have been collectively labeled simians. They are comparatively large in size (modal body weight approximately 5 kg), and almost all species are diurnal. Indeed, the only nocturnal simians are the New World owl monkeys (eight species of *Aotus*). The 10-fold difference in modal body size between simians and prosimians – 5 kg versus 500 g – is undoubtedly connected with the general distinction between nocturnal and diurnal habits. This is just one example of the pervasive importance of body size in primate biology. So the availability of a compilation of body weights for almost all primate species, very largely derived from wild animals, merits special mention (Smith and Jungers, 1997). Overall, living primates cover a 300-fold range of body sizes, extending from 40 g for the smallest of the lesser mouse lemurs (a species of *Microcebus*) to 120 kg for an adult male gorilla. Differences in body size account for many of the differences seen between primate species.

Definition of Living Primates

It is often stated that living primates represent a graded series, ranging from relatively primitive to very advanced, and that therefore it is difficult to demarcate them from other orders of mammals (notably Insectivora, which often have been seen as the most primitive placental mammals alive in the twenty-first century). This view, however, was influenced heavily by the inclusion of tree-shrews in the order Primates. Detailed reexamination of primates to the exclusion of tree-shrews revealed that all extant species in fact share a substantial set of characteristics. That shared set of features distinguishes primates fairly clearly from other placental mammals, as is indicated by the following definition (Martin, 1990, pp. 639–640):

> Primates are typically arboreal inhabitants of tropical and subtropical forest ecosystems. Their extremities are essentially adapted for prehension, rather than grappling of arboreal supports. A widely divergent hallux (big toe) provides the basis for a powerful grasping action of the foot in all genera except *Homo*, while the hand usually exhibits at least some prehensile capacity. The digits typically bear flat nails rather than bilaterally compressed claws; the hallux always bears a nail. The ventral surfaces of the extremities bear tactile pads with cutaneous ridges (dermatoglyphs) that reduce slippage on arboreal supports and provide for enhanced tactile sensitivity in association with dermal Meissner's corpuscles. Locomotion is hindlimb-dominated, with the center of gravity of the body located closer to the hindlimbs, such that the typical walking gait follows a diagonal sequence (forefoot precedes hindfoot on each side). The foot is typically adapted for tarsi-fulcrimation, with at least some degree of relative elongation of the distal segment of the calcaneus, commonly resulting in reverse alternation of the tarsus (calcaneo-navicular articulation). The visual sense is greatly emphasized. The eyes are relatively large and the orbits possess (at least) a postorbital bar. Forward rotation of the eyes ensures a large degree of binocular overlap. Ipsilateral and contralateral retinofugal fibres are approximately balanced in numbers on each side of the brain and organised in such a way that the contralateral half of the visual field is represented. Enlargement and medial approximation of the orbits is typically associated with ethmoid exposure in the medial orbital wall (though there are several exceptions among the lemurs). The ventral floor of the well-developed auditory bulla is formed predominantly by the petrosal. The olfactory system is unspecialized in most nocturnal forms and reduced in diurnal forms. Partly because of the increased emphasis on vision, the brain is typically moderately enlarged, relative to body size, in comparison to other living mammals. The brain of living primates always possesses a true Sylvian sulcus (confluent with the rhinal sulcus) and a triradiate calcarine sulcus. Primates are unique among living mammals in that the brain constitutes a significantly larger proportion of fetal body weight at all stages of gestation. Male primates are characterised by permanent precocial descent of the testes into a postpenial scrotum; female primates are characterised by the absence of a urogenital sinus (i.e. urinary and reproductive tracts entirely separate). In all primates, involvement of the yolk-sac in placentation is suppressed, at least during the latter half of gestation. Primates have long gestation periods, relative to maternal body size, and produce small litters of precocial neonates. Fetal

growth and postnatal growth are characteristically slow in relation to maternal size. Sexual maturity is attained late and life-spans are correspondingly long relative to body size. Primates are, in short, adapted for slow reproductive turnover. The dental formula exhibits a maximum of 2.1.3.3/2.1.3.3. The size of the premaxilla is very limited, in association with the reduced number of incisors, which are arranged more transversely than longitudinally. The cheek teeth are typically relatively unspecialized, though cusps are generally low and rounded and the lower molars possess raised, enlarged talonids.

An additional distinctive feature should be added to this definition (Sussman, 1999): All living primate species live in fairly elaborate social networks. Initially, nocturnal primate species were labeled 'solitary' because many of them tend to move around alone at night. But countless field studies have since shown that they all have well-established patterns of social interactions based on shared ranges, communal nesting, and regular encounters over the course of the night. Although there are no immediately recognizable social groups of the kind found in all diurnal primates except the orangutan, there are nonetheless long-lasting associations between individuals. The pronounced social tendency now recognized for all primates is surely connected with the high level of investment in individual offspring (including intensive parental care) and relatively long life spans that characterize primates.

The distinctive set of characteristics shared by living primates reflects a suite of adaptations developed in their common ancestor. Taken in combination with various primitive features that can be inferred for the ancestral condition, such as relatively small body size and nocturnal habits (Martin, 1990), they permit a plausible reconstruction of the earliest primates. They were probably small-bodied, nocturnally active arboreal creatures that were particularly well adapted for exploitation of narrower branches away from main tree trunks (the fine branch niche), where they fed on a mixed diet of insects and fruit. Inclusion of fruits in the diet accounts for certain modifications of their cheek teeth. Leaping and running among the narrow-diameter terminal branches of trees and among lianas would account for their typical nail-bearing, grasping extremities, notably the prehensile foot. It also provides an explanation for emphasis of the visual sense, with large, forward-facing eyes and specialization of the brain for highly effective visual orientation. Predation on small animals in the network of fine branches doubtless also influenced the conspicuous development of the visual system that characterizes the primates (Cartmill, 1992; Cartmill et al., 2007). Development of prehensile extremities also involved a shift toward use of the hands rather than the snout in grasping food items, thus explaining shortening of the snout and the associated reduction in number of incisors. Adaptations for low reproductive turnover and high investment in individual offspring can be interpreted as responses to life under the relatively stable and predictable conditions of tropical forests combined with comparatively low predation levels among fine branches.

Phylogenetic Relationships among Living Primates

Encouragingly, pioneering analyses based on chromosomal and molecular data broadly confirmed reconstructions of phylogenetic relationships of primates based on morphological evidence, leading to the emergence of a general consensus (Martin, 1990). Although certain relationships in the primate tree remained controversial, notably with respect to early divergences, this confirmation, stemming from largely independent analyses of new data, provided valuable support for earlier phylogenetic reconstructions based exclusively on morphological evidence. Because very deep divergences are involved, however, the pattern of relationships between primates and other mammals remained uncertain and therefore controversial. Over the past two decades, there has been a dramatic increase in information from molecular comparisons, especially because of burgeoning results from direct sequencing of DNA, in some cases extending to the sequencing of entire genomes. As far as primates are concerned, this has led to further confirmation of the general pattern of phylogenetic relationships among them and to resolution of several aspects that had remained questionable. As far as mammals in general are concerned, the molecular evidence has led to the construction of overall trees that have yielded an entirely new perspective on the relationship between primates and other mammals.

Taking primates first, the substantial body of evidence now available clearly confirms that the five natural groups of extant primates (lemurs, lorises and bushbabies, tarsiers, New World monkeys, Old World monkeys, apes, and humans) are phylogenetically distinct subunits within the tree (**Figure 2**). In other words, each of the five natural groups is monophyletic (derived from a specific common ancestor within the tree). As far as lemurs and lorises are concerned, the question of monophyly remained controversial for some time. This was because certain cranial features led several authors to suggest that mouse and dwarf lemurs in the family Cheirogaleidae are more closely related to lorises and bushbabies than to other lemurs. In fact, a review of chromosomal and molecular evidence eventually provided quite convincing evidence that the lemurs form a monophyletic group distinct from a second monophyletic group containing lorises and bushbabies (Yoder, 1997). Since that time, numerous comparative analyses of DNA sequences have confirmed the monophyly of lemurs and lorises, notably in a study that included every extant primate genus (Goodman et al., 2005). Together, lemurs, lorises, and bushbabies constitute a more inclusive monophyletic group (**Figure 2**). Members of this group are known as strepsirrhines, because of their common retention of a rhinarium (a naked, moist area of skin surrounding the nostrils in the primitive mammalian condition).

The position of the tarsiers in the primate tree has long been a controversial issue. Traditionally, tarsiers were included in the suborder Prosimii along with lemurs and lorises. This largely reflected the fact that prosimian primates have retained numerous primitive features and naturally will resemble one another for that reason alone. Comparative morphological studies increasingly revealed that tarsiers share a number of significant derived features with higher primates (traditionally allocated to the suborder Anthropoidea). In fact, the earliest evidence for an evolutionary link between tarsiers and higher primates came from comparative studies of placentation at the end of the nineteenth century. Lemurs, lorises, and bushbabies uniformly have a noninvasive (epitheliochorial) type of placentation, contrasting starkly with the highly invasive

Figure 2 Outline phylogenetic tree of extant primates (excluding tree shrews) showing the likely pattern of relationships among the five monophyletic natural groups, which are all descended from the last common ancestor of primates (node 1). Traditional classifications distinguish between the generally more primitive prosimians (Prosimii) and the simians or higher primates (Anthropoidea), which are characterized by a set of more advanced features. Because there is now convincing evidence that tarsiers are related to higher primates , however, many classifications now have the two suborders Strepsirrhini (lemurs, lorises, and bushbabies) and Haplorhini (tarsiers and higher primates). It is now generally accepted that the higher primates are monophyletic, with a distinct common ancestor (node 2) and that Old World monkeys, apes, and humans form a lower level monophyletic group with a more recent common ancestor (node 3).

(hemochorial) placentation characterizing tarsiers and higher primates.

Evidence from placentation was progressively complemented with the identification of striking similarities between tarsiers and higher primates in the olfactory system, the visual system, and the brain. But many authors remained unconvinced by all of these similarities. In this case, too, the controversy was resolved gradually by accumulating molecular evidence, beginning with immunological comparisons, passing through studies of amino acid sequences in proteins and eventually culminating in analyses of DNA sequences. Before the advent of DNA sequence information, an overall review of evidence (Martin, 1990) indicated that tarsiers are, indeed, the sister group of higher primates. But doubt persisted thereafter because mitochondrial DNA (mtDNA) sequences failed to support a link between tarsiers and higher primates. This aberrant outcome has been shown to be the result of an unusual pattern of evolutionary change in the mtDNA of tarsiers (Schmitz et al., 2002). There is now overwhelming evidence from the studies of nuclear DNA sequences that tarsiers are, indeed, the sister group of higher primates. A study using vast amounts of sequence data from the nuclear genome (Jameson et al., 2011) clearly separated tarsiers from strepsirrhines and linked them to higher primates instead. In other words, tarsiers and higher primates together constitute a higher level monophyletic group of primates. They are collectively known as haplorhines because (uniquely among mammals) they share complete suppression of the rhinarium.

In the realm of molecular comparisons, particularly valuable information has emerged from studies of retroposons in primates and other mammals. These are DNA sequences, often of retroviral origin, that are inserted into the nuclear genome. Many are relatively short sequences known as SINEs (short interspersed elements). As far as is known, retroposons are inserted at random sites in the genome and subsequently are not eliminated. Insertion sites hence serve as identifiable characters that are virtually free of convergence or reversal. One prominent group of SINEs found only in the primate genome is constituted by Alu sequences. Detailed investigation of Alu insertions in primates has revealed that tarsiers and higher primates share several unique retropositions that are lacking in strepsirrhines (Zietkiewicz et al., 1999; Schmitz et al., 2005). When this evidence from site-specific insertions is seen in conjunction with that from numerous studies of other nuclear DNA sequences, it now seems virtually certain that tarsiers and higher primates are sister groups.

The overall pattern of relationships between the major groups of primates has now become relatively clear. On one side of the primate tree, it has generally emerged that Lemuriformes and Lorisiformes are sister groups (i.e., their individual common ancestors were derived from an earlier common ancestor). On the other side, it has also generally emerged that tarsiers are linked to higher primates and that the latter (monkeys, apes, and humans) together constitute a distinct monophyletic group.

Before the availability of molecular evidence, there was in fact some doubt regarding a monophyletic origin of higher primates. On morphological grounds, several authors proposed that New

World monkeys on the one hand and Old World monkeys and apes on the other descended separately from prosimians that lacked certain defining features of higher primates. In other words, it was suggested that key similarities between modern New World and Old World higher primates arose through parallel evolution. From the outset, however, molecular evidence has consistently and unequivocally indicated that higher primates belong to a monophyletic group. Although molecular evidence has not permitted identification of the morphological characters present in the common ancestor of higher primates, it does indicate the existence of a long branch between the divergence of tarsiers and the emergence of that common ancestor. Molecular evidence consistently has indicated that New World and Old World higher primates are monophyletic sister groups. Moreover, within the Old World cluster, Old World monkeys and apes (including humans) have also been identified as lower level monophyletic groups in every study that has been conducted.

Molecular evidence has been crucial for the identification of higher level relationships among mammals. Although many attempts have been made to identify such relationships from morphological evidence, no clear consensus developed. Indeed, in some cases in which several morphological studies began to suggest a consensus interpretation, notably in linking bats to colugos (Volitantia), molecular evidence has yielded directly conflicting results. In the course of a little more than a decade, large-scale molecular studies across mammals have led to a fairly clear consensus interpretation regarding relationships among the 18 extant orders of placental mammals. In particular, it was quite soon recognized from analyses of DNA sequences that there are four main clusters of placental mammals (Murphy et al., 2001; Springer et al., 2004). Subsequent studies, notably including analyses of SINEs (Nishihara et al., 2006), repeatedly have confirmed this basic phylogenetic pattern, as indicated in a seminal synthesis of abundant available DNA evidence (Bininda-Emonds et al., 2007). The four superordinal clusters that have consistently emerged are (1) Afrotheria (aardvarks, afrosoricid insectivores, elephants, elephant-shrews, hyraxes, and sirenians); (2) Euarchontoglires (colugos, lagomorphs, primates, rodents, tree-shrews); (3) Laurasiatheria (artiodactyls with cetaceans, bats, carnivores, eulipotyphlan insectivores, perissodactyls, and pangolins); and (4) Xenarthra (a single order including anteaters, armadillos, and sloths). Among other things, this arrangement plainly rules out any phylogenetic link between bats and colugos, as the former are included in the superorder Laurasiatheria, while the latter belong to the superorder Euarchontoglires. Although the superordinal cluster Euarchontoglires has emerged consistently from molecular studies across mammals, relationships within that cluster have remained somewhat labile. The consensus of available evidence indicates that colugos are most likely to be the sister group of primates within a cluster known as Archonta, while lagomorphs and rodents are sister groups within a second cluster known as Glires. Several studies have linked tree-shrews and lagomorphs as sister groups. Regardless of the actual pattern of relationships within Euarchontoglires, the inclusion of colugos is a striking innovation. It has rarely been suggested on morphological grounds that colugos have any relationship to primates, and they have generally been completely ignored in discussions of primate evolution. Clearly, this must change.

The Primate Fossil Record

The known record of reliably identified fossil primates dates back to the beginning of the Eocene epoch, about 55 mya (Hartwig, 2002). An assemblage of earlier fossil forms mainly from the Paleocene epoch (65–55 mya), collectively labeled 'archaic primates' (Plesiadapiformes), traditionally has been allocated to the order Primates. These early fossil forms (some of which survived into the Eocene) show few, if any, of the features in the definition of primates given above, and their connection with primates remains questionable. Even if plesiadapiformes did have some early connection with primates, they undoubtedly diverged before the origin of 'primates of modern aspect' (euprimates), which include extant primates and their direct fossil relatives. Because plesiadapiformes are a side-group that diverged at such an early stage, they are of little relevance to the later adaptive radiation of euprimates.

Excluding Plesiadapiformes, the currently documented primate fossil record is divided fairly sharply into two segments separated by a gap of at least 6 million years in the middle of the Oligocene epoch (35–25 mya). Approximately equal numbers of fossil primate species (about 250) are known from each half of the record. Initially, primates of the Eocene epoch (55–35 mya) were documented only by early prosimians from Europe and North America. On both continents, they can be divided fairly clearly into two families, generally larger lemurlike Adapiformes (e.g., *Adapis* in Europe, *Notharctus* in America), and generally smaller tarsierlike Omomyiformes (e.g., *Necrolemur* in Europe, *Shoshonius* in America). Many authors have linked adapiforms to strepsirrhines and omomyiforms to haplorhines. Almost the entire skeleton is known for *Notharctus*; it is lemurlike and certainly demonstrates that many defining features of modern primates were present at that stage. Unfortunately, the postcranial skeleton of omomyiforms is poorly documented in the known fossil record, although several associated elements of *Shoshonius* have provided useful information regarding skeletal morphology.

This long-established record from America and Europe has been radically modified by more recent fossil finds from North Africa, Asia, and Southeast Asia. In North Africa, fossils from the latest Eocene and early Oligocene, notably from the Fayum site in Egypt, have documented the presence of a variety of early simians (e.g., *Aegyptopithecus* and *Apidium*) along with some potential relatives of modern strepsirrhines and tarsiers. Adding to the picture, Chinese middle Eocene fossil deposits have yielded evidence of early simians (*Eosimias*) and a putative direct relative of modern tarsiers (*Tarsius eocaenus*), along with adapids and omomyids. A well-preserved skull of an early Eocene omomyiform, *Teilhardina*, has also been reported from China. Moreover, late Eocene sites in Myanmar and Thailand have yielded several fossil simians (e.g., *Amphipithecus* and *Siamopithecus*), although they are almost exclusively known from jaws and teeth. Overall, the fossil record now shows that both prosimians and simians were present in the Eocene.

Figure 3 Overall phylogenetic tree of primates (excluding tree-shrews) showing the likely pattern of relationships among the five monophyletic natural groups of living primates. This tree also includes major groups of fossil representatives. Note that no direct connection between plesiadapiformes and 'primates of modern aspect' is shown because evidence for such a link is questionable. The initial date of divergence for primates of modern aspect is set at about 80 mya. Reproduced from: Martin, R.D., 1993. Primate origins: plugging the gaps. Nature 363, 223–234; original illustration by Lukrezia Bieler-Beerli.

Things are entirely different in the second half of the primate fossil record, extending from the late Oligocene to the present day. Direct fossil relatives of New World monkeys are known from South America, beginning in the latest Oligocene (*Branisella*) and extending into the Miocene (e.g., *Homunculus*). In the Old World (notably Africa), early Miocene deposits have yielded fossil relatives of bushbabies and lorises (e.g., *Progalago*) and of monkeys and apes (e.g., *Victoriapithecus* and *Proconsul*). A few fragments of tarsiers have been reported from Miocene deposits in Thailand. Thus, four of the five extant natural groups of primates can be traced back to about 25 mya, and one (tarsiers) can be tentatively traced back to 40 mya. Nevertheless, there are also notable gaps in the known fossil record. The most striking gap is in Madagascar, where no single fossil from the major radiation of lemurs is known prior to the recently extinct subfossils. Similarly, in the New World, no single fossil form can be linked reliably to the marmosets and tamarins, a substantial proportion of the modern species.

Gaps in the fossil record influence directly the inferred date for the origin of primates. The standard practice has been to assume that primates diverged during the Paleocene epoch, perhaps 60–65 mya, just a few million years before the earliest primates known from the fossil record. Direct inference from the known fossil record inevitably leads to serious underestimation if there are substantial gaps in the fossil record, as is undoubtedly true of primates (Martin, 1993). Several studies that calibrated molecular phylogenies for mammals using various dates for fossils of well-documented groups outside the primates have all concluded that primates diverged from other mammals about 90 mya. Allowing for some elapse of time between this initial divergence from other mammals and initiation of the adaptive radiation leading to the array of extant primates, this would imply that their last common ancestor existed about 80–85 mya (Figure 3). Two analyses of the primate fossil record that explicitly allowed for the existence of gaps have yielded a very similar date (Tavaré et al., 2002; Wilkinson et al., 2011).

Abstract

'Primitive' is a term from the evolutionary vocabulary of the nineteenth century that in popular understanding still identifies the interests of the modern discipline of anthropology. Anthropologists have sought to come to respectful terms with their 'Primitive' subject matter by redefining it in terms of a distinctive social structure, culture, spatial distribution, and type of livelihood. But despite efforts to set aside disparaging contrasts between primitive society and modern civilization, evolutionary assumptions about human progress remain embedded in both scientific and humanistic approaches to society.

In popular usage, 'primitive society' distinguishes ourselves from other people who have made little progress toward what we understand as civilization. There are very few such people left today: they live in scattered communities in deserts or rainforests, and they interest us mainly because we think of them as the living relics of our own distant ancestors. The comparison is usually unflattering. Until the beginning of the nineteenth century 'primitive' simply meant 'first' or 'earliest,' but as the word was applied to the original inhabitants of territories colonized by European and American states, it acquired the connotations of inferior, backward, rude.

In the evolutionary social science which developed toward the end of the nineteenth century, 'primitive society' came to be regarded as the defining subject matter of the emerging discipline of anthropology. The new natural science of biology provided the basic inspiration, and physical anthropology remains one of the four subfields of the discipline. However, although physical (or 'biological') anthropologists are much concerned with comparisons among primates they no longer distinguish human bodies as more or less primitive. We vary from one population to another in average body size, skin color, hair type, etc., and people within each community (neighbors or family members, young and old) look unalike, but unless we wish to be regarded as 'racist' we studiously avoid implying that any of these differences connotes inferiority or even some sort of adaptive advantage. Physically we are neither less 'primitive' nor more 'modern' than our ancestors 50–100 000 years ago.

It is, therefore, somewhat ironic that Darwinian hypotheses of the 'ascent of man' by natural selection have provided such a tenacious metaphor for distinguishing among human societies and cultures. For most social scientists for most ofthe twentieth century, being 'primitive' was a relative judgment about how people think and behave, not about their genes, brains, or bodies. Nineteenth-century explanations of social evolution construed Western civilization not just as the most successful human adaptation, but also as an inevitable and morally necessary path of progress.

While metabolizing or copulating might have changed little over the millennia, there were certainly more and less civilized ways of dining or marrying. And it was significant that only civilized modern man had the capacity to understand and explain the difference.

The first generation of modern anthropologists sought a general, empirically valid definition of the 'primitive,' and used the word without inhibition. Tylor's article defining anthropology in the famous 11th edition of *Encyclopedia Britannica* (1911) may represent the apogee of the technical use of the term. Thereafter, 'primitive' continued to appear in the title of ethnographic monographs, more as a generic label for subject matter than as an analytical concept. By the middle of the twentieth century, even the label had gone out of favor in the social sciences. The dissolution of the European empires and the emergence of new, transnational political-economic interests brought a shift in intellectual attitudes. Ideas of 'underdevelopment' as a natural, primitive condition which would be relieved by technically-enhanced progress toward modernity, soon yielded to ideas of 'underdevelopment' as a political-economic predicament inflicted on citizens of the 'Third World' by the expansion of industrial capitalism from its metropolitan centers. Peoples in the new states who were once classified as 'primitive' were now identified as the least privileged members of a widely distributed 'Fourth World,' which included the impoverished citizens of 'developed' countries.

The only entry under 'primitive' in the 1968 counterpart of this *Encyclopedia* referred to naive styles in art. 'Primitive society' has resurfaced in the present work as a historical curiosity rather than as current terminology. The phrase says more about changing interests, attitudes, and theories in anthropology than about the peoples to whom it once referred. In trying to come to terms with their designated subjects during a century of radical social change, anthropologists have buried 'primitive' society in layers of definition. These include specification of a distinctive sort of social structure, mode of livelihood, spatial distribution, and mentality, all defined (tacitly or explicitly) by a contrast with, and presumed progress toward, civilization as we understand it. Very occasionally an anthropologist will resort to 'primitive' as a portmanteau term: Hallpike (1976) uses it 'simply as a convenient abbreviation for "non-literate, small-scale, face-to-face-societies with subsistence economies." Although the pejorative implications are resisted sternly, there is still an evident need to refer contrastively to people who have not yet been absorbed within the ambit of 'literate, large-scale, impersonal societies with industrial economies.' Rejecting one word around which a discipline was constructed is not enough to dismiss the assumptions about evolutionary progress which linger on in our understanding of the differences between 'Us' and the sorts of people who are 'Our' anthropological subjects.

Livelihood

The simplest and least obviously offensive definition of the primitive has been the material circumstances of their lives. Anthropology as a discipline is still organized around a sequence of social types based on technical developments in the means of production. The prototypical human population of 'hunter-gatherers' lived in nature, taking what they needed day-by-day, whereas subsistence farmers were obliged to work on nature with tools and skills, taking possession of land and other resources, and thereby setting in motion the larger political and economic organization of the state. Technical complexity increased the division of labor, which produced societies in which larger numbers of people depended on more specialized functional relationships with each other. This was especially true of the second great technical revolution which began with the industrialization of cloth production in northwest Europe toward the end of the eighteenth century. With capitalism as its social vector, industrialism swept out to transform the world, creating among other things a new and palpable contrast between the modern and the primitive. It also produced the first generation of social scientists whose role in the ever-expanding division of labor was to explain what was going on.

Social Structure

In the pattern of evolutionary contrasts which emerged in the writing of Morgan, Tylor, Rivers, and the other early anthropologists, the social world of the primitive was the small, technically, and socially 'simple' community. In this evolutionary formulation, 'primitive society' was almost a contradiction in terms, "society" being seen as the multiplication of roles and relationships in expanding populations, with heterogeneous individuals bound by new forms of rational contract into complex entities like the modern nation state. The primitive, by contrast, was a 'society of clones' (Kuper, 1988), held together 'mechanically' (Durkheim's term) by the relations of reproduction. Social anthropologists pieced together the logic of systems of descent and marriage which apparently gave these 'homogeneous' communities their cohesion. For example, the simple rule 'reckon that you are the child of your father rather than your mother' was enough to tease a whole population out into mutually-exclusive (patri-) lineages, conferring distinct political identities on people who might never actually meet each other. Debates raged about whether paternity or maternity was the more primitive mechanism of social solidarity. The 'elementary structures of kinship' (clans, demes, moieties, etc.) conferred statuses and roles by birth, but these 'ascribed' relationships were less useful as people were drawn into much larger fields of interaction in technically more advanced societies where survival and progress depended on geographical movement and the exercise of choice and imagination.

Governed by the biologically-derived moral mechanisms of kinship, the primitive tribe could manage without officials and rulers. From an imperial perspective, these emerging definitions of the 'tribe,' boosted by romantic writings of the period, were both intellectually attractive and administratively useful. The tribe suggested a prototypical democracy, a predominantly male political structure, and a paradigm of nationalism – the great seductive and destructive passion of the twentieth century. After two world wars which revealed the barbarity of civilization and cast doubts on who was more primitive than whom, the natural logic of the 'tribe' (as expounded, e.g., by Evans-Pritchard for *The Nuer* (1940) of the southern Sudan) was appealing. In the 1968 *Encyclopedia*, 'Primitive society' was broken down into seven cross-references: Anthropology, Culture, Evolution, Hunting and Gathering, North American Indians, and – the principal entry – Tribal Society. However, the 'Tribal' label could not stick. The year 1968 also brought the revival of the intellectual left, and the association of 'tribalism' with the ideologies and practices of imperialism quickly made it taboo. Anthropologists were now being accused of complicity in the task not just of identifying but inventing the tribes which had been the units of European and North American colonial government.

At this time, the other substitution for 'primitive' was traditional, the preferred counterpart for modern in the evolutionary scheme. But very soon this too was found to be pejorative, mainly because the innumerable books juxtaposing the two words in their titles seemed to presume an ethnocentric convergence on a Euro-American paradigm of modernity. 'Traditional societies' were scattered and diverse, stuck in the inertia of custom until history drew them inexorably into the global monotype of 'modern society.' In the 1980s such teleologies of modernization were rejected by scholars who defined themselves philosophically as postmodern. They wrote critically of our historic and ideological self-centeredness and in praise of a diverse category of 'The Other,' which stood mostly against the hegemony of (Western) scholarship itself. An emblematic study was Clastres's (1977) account of the Tupi-Guarani indians of the Amazon, whose profoundly primitive social structure supposedly set up antibodies for the development of inequality, leadership, capitalism, the state, and the other vices of modern civilization. Such writing paved the way for a revival of sympathetic interest in the 'primitive.' Postmodern characterizations of 'Otherness' invoked a much older assumption about primitive society: its spatial isolation. Earlier anthropologists had pursued the prototypical primitive to the ends of the earth, especially Australia and Oceania, and ethnographic accounts of these tiny encapsulated communities in turn fleshed out the definition of 'primitive.' Postmodern anthropologists pointed out that the (relatively) concerted forces of worldwide capitalism had tended to marginalize people physically remote from the metropolitan centers, making 'peripheralness' a common denominator of what had hitherto been called traditional, tribal, or primitive. The desire to see 'Others' entirely in their own terms as just 'different' not only meant abandoning pernicious comparisons with 'Us' but also the assumption that the 'Others' had anything specific in common among themselves – some generic sort of 'traditional' culture or 'primitive' social structure.

Most problematically, it was not even safe to assume that everyone had essentially the same sort of body, because biology or physiology themselves were only historically specific sets of ideas for coming to terms with the human condition. This deliberate affront to science has exacerbated a split in anthropology, set in motion by the invention of 'sociobiology' in the

1970s. With 'evolutionary psychology' as the link, a new genre of anthropology is pursuing genetically endowed physical mechanisms which shape culture, for example, through the processes of language acquisition or mate selection. From this point of view, 'primitive society' as represented by today's vanishing hunter populations are living testimony to the 'Environment of Evolutionary Adaptedness' in which modern man was physically constructed and mentally endowed. Virtual banking or an appreciation of Beethoven is fundamentally as 'primitive' as gnawing bones. These exciting speculations have captivated public attention, putting the denser, relativistic theories of idealist anthropologists at a disadvantage.

However, it is ironic that the radically Cartesian post-modern approaches to society have taken the psychic unity of human beings entirely for granted: it is not our minds which differ, but the way they are culturally made up. This returns us to some very old and persistent mental assumptions underlying the meaning of 'primitive' in its various transmutations.

Mentality

In drawing analytical metaphors from biology or botany the social sciences and humanities have not always kept pace with theoretical advances in the natural sciences themselves. The nineteenth century evolutionist idea of recapitulation was absorbed by the emerging social sciences, and lingers as a latent assumption about human behavior in forms which biological scientists would now barely recognize. The original formula, as specified by Ernst von Haeckel, was that the life history of the individual organism repeats, from the embryo onward, the stages of its species evolution ('ontogeny recapitulates phylogeny'). Transposed to the social domain, this fostered the notion that children are primitive – and, by a facile converse, that primitives are children. Thus, Lubbock (1875) was fascinated by 'The similarity of savages and children,' and struggled to prove that the childish trait of phonetic reduplication (words like *bonbon)* was an infantile characteristic of primitive languages, absent from civilized English, French, German, and Greek. For social philosophers like Henry Sumner Maine, primitive society was 'the infancy of man,' and as late as 1953 Robert Redfield commended the human race for its tendency 'to grow up.'

The metaphoric transfer of this early biological concept to society and culture continues to create much confusion. Although it is implausible that a modern child could be reliving the traumatic experiences of ancestral adults, the idea that children relive primitive urges remains at the heart of Freudian psychology. Indeed, in his study of *Totem and Taboo* Freud (1938[1919]) pursued the argument to 'resemblances between the psychic lives of savages and neurotics.' The logic of recapitulation leads inexorably to the conclusion that the metamentality of 'culture' is, for primitive people, childish and crazy, and that their world is a kindergarten which can only benefit from some civilized parenting – a good excuse for colonization and imperialism. This elaborate equation of the mad, the childish, and the primitive is extraordinarily tenacious, despite many attempts to sort out the confusion. Margaret Mead, for example, sought to demonstrate that primitive Melanesian children were actually 'more rational' than their 'animistic' parents. This subverts Enlightenment assumptions that rationality increases as a function of both of individual and species development. But for such a devout idealist and anti-evolutionist as Mead, it also raises disturbing question about how children everywhere come ready-equipped with this sort of scientific rationality, and think straight until 'enculturation' fills their primitive minds with superstitious rubbish.

Anthropologists have always traded on public fascination with the magic and superstition we associate with primitive (and childish) thought. Given its persistence in modern society, religion itself has not been an acceptable marker of the primitive. The discriminating variable here is, once again, scale: the universalistic 'World Religions' (Christianity, Judaism, Islam) deal with the mass of individual souls, while the narrow-minded particularistic religions of primitive society connect people spiritually to community and locality ('animism,' 'fetishism') often through the biosocial idiom of descent ('ancestor worship,' 'totemism'). These peculiarities of primitive thought have interested French anthropologists particularly, immersed as they are in the idealist tradition. Inspired by Franz Boas, Kroeber, Mead, Benedict and other American anthropologists tried very explicitly to reject the evolutionary premises, and pursued a relativistic interpretation of culture (rather than 'society') which sought to avoid the prejudices of a superior western civilization. However, the central conundrum of relativism seems inescapable: how can we distinguish one culture from another if we have no agreed definition (some sort of 'metaculture') of what culture is in the first place? Simply to insist that all human beings have the mental capacity to 'do' culture evades the issue of how that capacity is physically embodied, how it constrains behavior, and (the evolutionary question) how and why we need it.

The most fundamental belief, which very few modern anthropologists would dare challenge, is of psychic unity, a conception of the human mind as inhabiting a standard brain which may determine how but not what we think. In the idealist tradition, what we think is determined outside of ourselves in an integral, self-reproducing system of ideas – culture, with a 'mind' of its own. The trouble is how to reconcile the enormous differences in culture with the primitive sameness of our minds. A symptom of lingering evolutionism has been the association of this primitive mentality with a closeness to nature.

This is captured in the old term savage, a synonym for primitive which appeared in anthropological titles well into the twentieth century, though increasingly in ironic quotation marks (Lévi-Strauss (1966) *The Savage Mind*; Goody (1971) *The Domestication of the Savage Mind*; LaFontaine (1981) *The Domestication of the Savage Male*, etc.). Although in French 'sauvage' still has a more benign, Rousseauian ring, the English connotations offierceness and intemperateness latterly made it at least as stigmatic as 'primitive.'

Seeking a general and objective axis of intellectual difference, many anthropologists have settled on literacy as a key technical distinction between primitive and modern mentality. Thus, in the early 1930s, Margaret Mead uses the word 'primitive' to refer to those peoples who are completely without the benefits of written tradition, and in 1953 Robert Redfield declared 'I shall use "primitive" and "preliterate" interchangeably' (he also used a range of cognate terms including 'folk' and

'precivilized'). By the 1970s pre- or nonliterate had become the favored term for the societies traditionally discussed by anthropologists, and it remains a key universal classification for those working in the idealist tradition.

Nostalgia

A final reason for the persistence of notions of the primitive within and beyond anthropology is plain old-fashioned nostalgia – the old image of the noble savage as a counterpoint to the vices of civilization. Anthropologists are notorious for their populist commitment to the people among whom they have their main (usually first) ethnographic experience. Indeed, it has often been said that anthropologists are people seeking a special sort of redemption in the notion that the moral virtue lacking in so-called civilized society may be rediscovered among simple people who are more in tune with nature. Defense of primitive peoples, usually in conjunction with the protection of their forest or desert environments, has become a respectable political commitment for many anthropologists. Despite Marx's rage against populist utopianism, his own material laws of history imagined a return to the perfect altruism of primitive society. This image of our natural selves before we were corrupted by the rise of capitalism was inspired by the ethnographic vision of 'Ancient Society' in North America constructed in the mid-nineteenth century by one of the founding fathers of anthropology, Lewis Henry Morgan. Marxists have been rebuked for urging the violent recovery of this old society without offering any plausible account of its structure. That it should somehow combine the benefits of the scale, technical expertise, occupational specialization and intellectual achievements of modern industrial society directly contradicts most of what has been learned about primitive society.

Today, the idea of the primitive lives on in a schizophrenia of admiration and disgust. On the one hand, popular writers like Robert Kaplan have promised the return of the modern world to barbarism, while anthropologists like Paul Richards explain that what appears as primitive lapses in Sierra Leone or Cambodia is a wholly modern circumstance – the global failures of industrial capitalism. In whatever guise, the concept of the primitive seems irrepressible in our imagination of ourselves, lurking in the shadows as we struggle to detach our vile, ancient bodies from the dream of a transcendent modern mind.

Printing as a Medium

Abstract

This article first defines printing as the mechanical reproduction of texts using a press. It then examines the history of the practice from Gutenberg to the industrial era, identifying three levels on which society sought to shape its development: the levels of domestic morality (within the printing house itself), craft organization (within the guild of master printers), and the polity (within the church and state). It outlines the regulatory mechanisms (patents, licenses, etc.) that shaped early printing, before briefly showing how those mechanisms, in collapsing, gave rise to modern legal regimes, especially copyright. The article then moves on to appraise social–scientific interpretations of printing's cultural impact. It describes the arguments of scholars including Jürgen Habermas, Marshall McLuhan, Elizabeth Eisenstein, Robert Darnton, and Roger Chartier. It concludes by suggesting that in future, as the unquestioned cultural dominance of print finally comes to an end, we may be more prepared to see its effects as deriving as much from our practices of reading as from a cultural logic that might have been imposed on us by the press itself.

Printing is a technique for producing all kinds of paper-based records (books, periodicals, musical scores, ephemera, etc.) by means of ink, a press, and reusable characters. It permits the mechanical production of many identical copies, thereby eliminating the corruption inevitable in hand copying. Printing has had profound consequences in all spheres of social life. In particular, it has often been ascribed a major role in the transition to modernity that took place in the Western world after the Renaissance.

The History and Impact of Printing

The Invention of Printing

Techniques for the mechanical reproduction of texts are not a uniquely Western invention. Such techniques existed in Korea and China hundreds of years before they did in the West. Yet, it is in the West that the press had its greatest impact. It is customary to divide the history of printing there into two periods: the hand-press era, lasting from the mid-fifteenth century to the early nineteenth; and the industrial era, beginning shortly after 1800 with the invention of the steam press and lasting into the present. Social scientists' arguments about the effects of printing as a medium tend to concentrate on the former, in an effort to help explain modernization in terms of a putative 'printing revolution.' But, as will be suggested below, they would often be more aptly applied to the latter.

There is no plausible route by which Asian technologies may have influenced Johann Gutenberg (*c*.1398–1468), a goldsmith from the Rhineland town of Mainz who built the first European press, so he may legitimately be called its inventor. At first, his intent was anything but revolutionary. When he constructed his first press, Gutenberg did so as a calculated intervention in the world of commercial manuscript production that already existed. His earliest printed books were designed to resemble manuscripts, and he intended to sell them as such. He also swore his workmen to confidentiality about his new technique, apparently, in the manner of apprentices in any late-medieval craft. But the strategy did not last. In 1462 Mainz was besieged and sacked, and Gutenberg's printing house broke up. His workers went to other towns and set up their own operations. Before long, printers had appeared in a score of German, Dutch, Italian, and French cities, often fostering legends that printing had been invented locally. Venice, Avignon, Strasbourg, and Haarlem created the most plausible of such histories, as a result of which determining the true origins of the press remained a notoriously intractable problem well into the nineteenth century. William Caxton set up his printing house in London at the end of this first wave of expansion. By that time, in 1480 or so, a new European craft was firmly established.

The Practice of Early Printing

That craft centered on the press – a simple, largely wooden machine, capable of being made by semiskilled workmen and, if small enough, amenable to concealment and transport from place to place. This press would normally be operated in a place called a printing house. Here, a compositor would set type into a frame called a form, which would then be placed in the press itself, which two pressmen would operate to make up to 1000 impressions per day. The resulting sheets would then be dried, and collated to make books. It sounds, and in essence it was, a simple process. But in practice, it was hard to sustain. Most printing houses were severely undercapitalized, and depended for their day-to-day survival not on the printing of books, but on that of ephemera and pamphlets – anything, in fact, that furnished regular and frequent influxes of cash. Almost all of these products were destroyed soon after manufacture. The population of books that has lasted to the present day to fill our great research libraries therefore represents an extreme distortion of the reality of early modern print culture.

This being so, printing raised an immediate question: whether culture could be allowed to be defined by commercial necessity. Early modern Europe attempted to answer that question by constraining printing on three social levels: the household, the craft, and the polity (where the polity might be a religious one, such as the Catholic Church).

In the first place, a printing house, like most places of work in early modern Europe, was normally supposed to

be a residence as well. The master printer generally lived in the same building – as, quite frequently, did his journeymen and apprentices. There was a reason why this was held to matter. It was conventional to believe that the moral structure of the patriarchal household largely guaranteed the legitimacy of practices pursued within that household, and printing was to be subjected to the same moral oversight.

In the second place, printing was also organized into guilds, one of which existed in every major city. To be a master printer was to be a respected member of such a group. Each maintained its own conventions, expected to be honored by all members of the book trade. Violations were identified and remedied by book-traders themselves, generally behind closed doors, so that for outsiders the image of an intrinsically harmonious order of print was sustained. Again, there was nothing strange about this; it was how all early modern crafts operated.

And in the third place, such guilds operated in fragile harmony with regulations imposed by the church and the state. Chief among these were 'privileges' (patents) and licenses. Privileges were grants of literary property, to use an anachronistic phrase, given out by the monarch or an equivalent authority. They conflicted in principle with titles allocated by the guilds internally, which was one reason why they were eventually replaced by copyright conventions. A license, on the other hand, was a permission to print (in Latin, imprimatur, 'it may be printed'), granted by an authorized individual to the printer or bookseller. In principle, all works had to be vetted by such an official before publication, but in practice this was rather less severe than the censorship sometimes portrayed by modern historians. Most books were never licensed, and only a tiny minority were pursued for lack of an imprimatur. The Counter-Reformation Catholic Church extended this principle of licensing into a systematic Index of Prohibited Books, which listed titles the ecclesiastical licensers had decreed too unsound for general readers. Again, while this undoubtedly affected the availability of certain books and authors (Machiavelli and Copernicus, for example) in Catholic lands, protestant publishers quickly realized that appearing on the Index virtually guaranteed best-seller status in their own countries, and they rushed to print large impressions.

In these ways, then, the social order of early modern Europe sought to accommodate the potentially revolutionary new craft. It was never an entirely stable arrangement, and by the late seventeenth century, it was breaking down. In England, first, licensing lapsed in 1695. With it went much of the authority of the local guild, called the Stationers' Company. Nobody wanted outright deregulation, however, and the major result was a hard-won new compromise between state, authorial, and trade interests. It was articulated in the so-called 'Copyright Act' (1710 – the term copyright never actually appears in it). This act became the basis for the entire subsequent history of copyright and intellectual property law. By the late eighteenth century, agitation for reform of printing and literary property on similar lines had occurred across Europe, and in the years around 1800 broadly similar copyright provisions were established in all major Western states; they extended beyond Europe and the colonies in the nineteenth century. The modern conventions of printed authorship thus owe their origin to the existence and instability of early modern attempts to define and regulate printing: to licensing, patents, and the craft practices of printers themselves (Chartier, 1992).

Industrial Printing

The technology of printing remained virtually unchanged from soon after Gutenberg's invention until around 1800. At that time, however, change came rapidly. Not only did the legal and conventional practices governing the industry alter once and for all; so did the technology of printing itself. First came Stanhope's metal press. This was soon followed by the steam press, which at a stroke increased production rates by an order of magnitude. Stereotyping finally made the dream of truly identical copies a reality. And at the same time, the technology of papermaking changed dramatically with the success of Henry and Sealy Fourdrinier's machines in Hertfordshire. Although it never had the iconic status of the steam press, the papermaking machine had as great a role in the changes of this period, and Brunel himself hailed it as 'one of the most splendid inventions of our age.' With the advent of all these new devices occurring within a generation, between 1800 and 1840 printing underwent its own industrial revolution.

The first commercial steam printing was done at the office of The Times in London. It vastly increased the print run of the newspaper, quite literally overnight (the management had the machines installed in secrecy to prevent unrest among the soon-to-be-redundant workers, and unveiled them only when they produced their first day's issue). Nor did the improvements cease there: by 1827 The Times had new presses that were producing 5000 copies an hour. Steam printing was understandably slower to take hold in smaller publishing markets, since it required a large capital outlay – Cambridge University Press, for example, was unusually avant-garde among specialist houses in adopting the technology, yet still did not do so for more than a generation. And in general, the book publishing business was less immediately affected by industrialization than the newspaper and periodical press. But the advent of industrial technology nonetheless changed printing forever, and vastly increased its social impact.

In fact, many of the attributes that historians and social scientists attribute to the hand press may more properly be assigned to the steam press, in conjunction with mechanical papermaking and stereotyping. Typographical fixity in particular was never as clear a component of hand printing as we tend, anachronistically, to assume – in an edition of perhaps 300–1000 copies, any number of variations would occur across different copies, as correction would be done on the fly. This kind of variability now ceased. Print runs 10 or 100 times as great as had previously been viable also represented a quantitative leap as great as that associated with Gutenberg. They made possible, indeed in economic terms virtually necessitated, the first national daily press. The development of mass literacy, too, was really much more a phenomenon of the nineteenth and especially twentieth centuries than of the sixteenth and seventeenth; mass education of the kind parodied by Dickens in Hard Times relied on steam printing. At the same time, since industrial printing required a great deal more concentration of capital than had hand printing, it encouraged agglomeration

and uniformity within the publishing industry itself. The press barons of the twentieth century, with their incalculable influence on social and political life, owed their baronies to the printing techniques introduced in the nineteenth century. In effect, printing had become a branch of factory culture.

A Printing Revolution?

Gutenberg's invention had profound social and cultural consequences, and modern historians and social scientists have tried hard to discover what they were. First and foremost, the press produced texts in unprecedented quantities. Lucien Febvre and Henri-Jean Martin (1958), in the first modern work to focus on the history and impact of printing, calculated that the number of printed books soon exceeded the number ever produced in manuscript up to that time. The sheer quantity of this order had its own consequences. Books were suddenly available in unprecedented numbers, in more places, and at lower costs. As they spread through social ranks, people – especially town-dwellers – made these new objects their own. Literacy increased markedly, and that alone constitutes one of the major turning points in the development of modern social order. But mere numbers cannot explain the more specific cultural consequences of the press. Major qualitative changes were also brought about by print. These have been described most exhaustively by Elizabeth Eisenstein (1979). They were of two major kinds: transformations in the making and appearance of the page, and innovations in the uses of books by writers and readers.

After Gutenberg's brief experiment with imitation, the printed page soon began to look very different from its manuscript predecessor. Typefaces and layouts became standardized. Cross referencing, indexes, errata, and notes came into use, according to conventions that themselves grew more uniform. Woodcuts and engravings allowed the use of repeatable images, permitting diagrams, charts, and scientific illustrations to be communicated with a security never before possible (Ivins, 1953; McKenzie, 1986). Hitherto, it had been very difficult to express sophisticated claims in pictorial form, so rapidly did images degrade in the hands of copyists. The simple ability to juxtapose and compare reliable representations of competing claims revolutionized the possibilities for learned work.

This textual 'fixity,' as Eisenstein calls it, affected a number of cultural realms, among which religion and science may be singled out. It is not a coincidence that Luther's reformation lasted, while previous attempts at reform (such as those of Hus, or the Lollards) had withered or been wiped out. The permanence and cornucopic plenty of print made Luther's program impossible to suppress. Indeed, it is in the furore over Lutheranism that some of the most characteristic forms of mass communication were invented, such as the pamphlet and the polemical cartoon (Scribner, 1981). And, most fundamentally, only such a machine could truly hope to permit a 'priesthood of all believers' by making the Bible available as an object to innumerable readers.

In the sciences too the advent of print permitted great upheavals. The contemplative natural philosophy of the schoolmen gave way before a newly active interrogation of natural processes, modeled, allegedly, on the practices of craftsmen. Print not only circulated this new natural knowledge but also helped to create it, since printers' homes became 'polyglot households' where scientists of all nationalities could meet and correspond. Print thus helped forge the norm of open communication that is so central to science. And men like Henry Oldenburg secured the status of the new science in novel forms of printed communication. Oldenburg's Philosophical Transactions, launched in 1665, survived to rank today as the oldest of all scientific journals.

But printed texts alone did not change the world; printed texts plus new ways of using them did. Not least, the sheer mass of printed matter required new classification techniques – in effect, a science of bibliography – to master a worldwide 'library without walls.' But more profound was the change in reading practices that print facilitated. From its early days, Philosophical Transactions was the central plank of a new, transnational readership of naturalists, gentlemen, mathematicians, and scholars – the ancestor of today's scientific community. The common readership of such periodicals was rapidly recognized as uniting a novel kind of collective, called the republic of letters or, rather later, the public sphere. This 'public' was defined by its engagement with print. And with Baconian ambition, it took all knowledge to be its province (Habermas, 1962). It marked a decisive break from traditional and absolutist societies. In Habermas' very influential account, it therefore laid the foundations for true sociopolitical transformation, most notably in the form of the French revolution. In that sense, the 'printing revolution' ushered in by Gutenberg warranted its name.

Theories about Print

It was in the context of the Jacobins that printing was first recognized as an explicitly revolutionary force. True, Francis Bacon's salute to the press (along with gunpowder and the mariner's compass) was much cited; yet it was little more than an aphorism. The first fully articulated and contextual interpretation of printing's impact was that of the Marquis de Condorcet (1795), who was seeking to explain the overthrow of the French monarchy. Condorcet sketched out a history of 'the human spirit' in a series of stages, with the invention of the press constituting a major turning point and effectively making the deposition of the Bourbons into 'the revolution that the discovery of printing must bring about.' In composing this sequence, he became the first writer to chart a trajectory of print-based modernization that saw its effects manifested first in the sciences, and only later in general social life. That trajectory has retained its persuasive power in modern times, but its meaning has been construed in very different ways.

Heirs to Condorcet, modern historians, and social scientists have continued to concentrate their interpretative efforts on the typographical ancient régime that came to an end with the dual inventions of copyright and the steam press. Compared with this, the period of industrial printing has received comparatively slight attention. There have been many empirical histories of printing, publishing, and reading in the nineteenth and twentieth centuries, but nothing as influential in social–scientific terms as Habermas or Eisenstein. Indicative is the

reception of Habermas' work on the public sphere: most Anglophone readers neglect its second half, which tells a depressing story of the replacement of Enlightenment public culture with industrial mass culture. His story is far more elegiac than celebratory, but one would not realize this to read most of the Anglo-American commentators on *The Structural Transformation* of the Public Sphere (1962).

Where they do not ignore the later history of printing, most scholars simply conflate it with the earlier history, and speak of 'print' as though it were a single, uniform entity. Probably the most famous and notorious of construals along these lines has been that of Marshall McLuhan (1911–80), the Canadian literary critic and scholar. McLuhan's *The Gutenberg Galaxy* (1962) and *Understanding Media* (1964) set the pattern for a series of works published in the 1960s that made extravagant claims for the cultural and even psychological impact of print. His works used what he called 'probes' – unsystematic, radical aphorisms delivered scattergun fashion to jolt readers out of the formulaic thinking that, he believed, typography inevitably instilled. The probes worked, in at least one sense. McLuhan himself became a cult figure: Tom Wolfe remarked that he sounded like "the most important thinker since Newton, Darwin, Freud, Einstein, and Pavlov."

What McLuhan achieved was to make 'media' the subject of analysis in their own right. He argued that these media, of which print was the archetype, brought the world together, dissolving boundaries. The most important of these boundaries were sociopsychic in character. Indeed, McLuhan's very definition of a medium was that it acted as an 'extension of man,' transcending the material constitution of the human frame. In effect, he believed that the state of media determined not only how humans lived, but what humans were. This he presented as a matter of evolution. In particular, McLuhan portrayed what he called 'typographic man,' namely the kind of being who lived according to the cultural logic of print. Typographic man thought in terms of linear logic and objectivity, because his reference points were fixed texts, in what later became the Eisensteinian sense of fixity. Typographic man was both individualist (he could be sure who he was) and nationalist (he could see the bounds of his community, and tell the difference consistently between it and others). There had been no such being before about 1450. At that point, typographic man had begun to displace 'tribal man,' who had been restricted to local contacts and communication by hand. And in his turn typographic man was now becoming extinct, to be replaced by something else that McLuhan himself left nameless, but who could easily be called 'electronic man.'

McLuhan remarked that it was in the nature of electronic media to integrate with the nervous system itself, establishing humans as nodes on a worldwide network. In effect, the skin itself would dissolve as a social constraint, as neurology became inseparable from sociology. Written in the early 1960s, before the first computer network, it is easy to see why McLuhan has recently been rediscovered by the digerati and labeled a 'prophet of the Web.'

Yet McLuhan's arguments were ultimately too faddish in their tone, and too determinist in their content, to remain convincing beyond their bare outlines. Criticisms soon started to mount (an influential example is Jonathan Miller's short 1971 introduction, which leaves little doubt where its author stands). There are few social scientists or historians today who would openly acknowledge McLuhan as a leading influence on their representations of print and its consequences. But that influence is nonetheless real. For the most part, it is refracted through the historical analysis of Eisenstein. Eisenstein's careful arguments about the impact of the hand press gave empirical weight to McLuhan's aphorisms. Through her, his proposals have gained academic respectability. An example is Benedict Anderson's widely praised account of nationalism (1983), which rests on an explicitly Eisensteinian argument linking print to time reckoning, and thence to consciousness of national identity. Similarly once removed arguments of this kind can be found in many of the analyses of 'print culture' to have appeared in the 1980s and 1990s.

Yet there is one important respect in which current trends in sociological and historical research are starting to depart consciously from this approach. This is the move toward an empirical history of the practice of reading. The immediate origins of this trend lie in France, where the postwar enterprise of the history of the book was born. The spur came from the responses of both history and sociology to the dominant Annales school. In both fields, a realization took hold in the later 1970s that quantitative social–scientific accounting failed to capture something fundamental about the cultural impact of print. At the same time, Pierre Bourdieu (1979) was emphasizing the importance of active cultural appropriation by readers of the press rather than passive cultural reception by those readers (Hoggart (1957) had earlier made similar arguments for an English readership). By the early 1980s it looked as though attention to the varied ways of using books, building on Bourdieu's approach, might stand a chance of seeing what the quantitative Annalistes were clearly missing. Since then the history of reading has become a burgeoning field in its own right.

The leading proponents of the history of reading have been cultural historians like Roger Chartier in France and Robert Darnton in the United States, who have pioneered the reinterpretation of the French Revolution in these terms. Chartier in particular objects to the determinism about print that is implicit in the work of Habermas, and would direct attention more to changes in reading practice in the eighteenth century (Chartier, 1990). In particular, he argues that it is difficult to understand how the scatological and pornographic literature that admittedly flooded eighteenth-century France was intrinsically more devastating to the priesthood, say, than the rich seam of libels that appeared in Luther's day. Instead, Chartier would point to a newly skeptical and extensive practice of reading that was devoted to these materials, making them far more damaging in use. This practice contributed substantially to the desacralization of kingship. It hence made regicide possible, and with it the origins of modernity. In this light, the printing revolution needs to be redefined as part of a broader reading revolution (Cavallo and Chartier, 1999).

As a result, research into printing as a medium is today leaving behind quasideterminist accounts of print exerting some kind of cultural 'logic' on societies, and toward empirical and historical research into the different ways in which societies have made use of the technology and its products. Important examples include the national histories of the book now being published in Britain, the United States, and other countries (Chartier and Martin, 1982–1986; Amory

and Hall, 1999; Hellinga and Trapp, 1999). D.F. McKenzie's 1984 study of a decisive cultural encounter mediated by print in his native New Zealand shows how this modern approach can influence anthropological understandings as well as historical. In McKenzie's terms, excessively schematic talk of "print logic" is being replaced by a properly contextual "sociology of texts" (McKenzie, 1986). It is interesting to speculate whether, with print logic thus banished, the use of 'print culture' as a catch-all explanatory device may eventually fall into abeyance too. And that may happen, not coincidentally, just as the advent of electronic media signals the end of half a millennium in which print was the predominant communicative medium.

Abstract

A distinctive sociology of prison life emerged when the prisons of North America and Europe became newly accessible to sociological and anthropological researchers in the 1940s and 1950s. It was to be characteristically informed by the structural-functionalism that was then prevalent, dwelling in particular on the apparent functional interdependence between prisoners and staff and between formal and informal social relations that seemed to sustain stable patterns of accommodation in authoritarian, coercive institutions. Its subsequent development was shaped by a succession of qualifications and elaborations that stressed how prisons differed from one another in their scale, regime, composition, and conceptions of prisoners' rights. Research in the area eventually atrophied as prison administrators became more defensive and less inclined to encourage close observation and as penologists and criminologists became intrigued by political economy and the broad historical writings of Michel Foucault.

The sociology of prison life concentrates on thick descriptions of the actions and accounting practices that make up the distinctive social organization of a prison. Chief amongst its preoccupations have been how administrators and staff strive to maintain an authority which can never be wholly legitimate in the eyes of their captives; how, in turn, those captives contend individually and collectively with conditions of deprivation and adversity, including the adversities inflicted by their fellow inmates (Morris and Morris, 1966, pp. 168–9); how a negotiated social order can emerge out of the exchanges between the two; and how, as a result, prisons manage to persist at all.

The proper study of prison had to await the emergence of universities and other institutions that could sustain social research, deploy some form of fieldwork as part of its methodology, and appreciate that the prison is a strange institution which 'challenges the anthropological imagination' (Sparks et al., 1996, p. 33). It was not until the 1940s and beyond that those three strands converged in what are commonly held to be the first significant pieces of writing about the sociology of prison life, Clemmer's (1940) *The Prison Community* and, perhaps more important, Sykes's (1958) *The Society of Captives* and Goffman's (1961) *Asylums*. Because they set a pattern and foil for much of what was to come, it is useful to recite their principal arguments.

The Prison Community reported research conducted in the 1930s in a penitentiary for adult felons by a sociologist attached to the mental health staff. Clemmer used the methods of anthropology to study what he called the 'facts of social life,' the groupings, patterns of leadership, controls, leisure pursuits, sex, and work of prison, and to illustrate the complex relations, and the informal relations in particular, of a predatory, suspicious and atomized world of inmates banded publicly against authority but privately riddled by informers and mistrust.

The Society of Captives depicted inmates suffering 'the pains of imprisonment' and striving for the goals of better food, more rewarding work, fuller information, access to sex and pornography, security, status, and autonomy, formally denied them by an administration that purported to treat all prisoners more or less alike and certainly completely distinct from staff. It was in this sense that prison was held to engender anomic pressures that led, in their turn, to the production of illegitimate stratagems, informal social structures and a code of conduct that could satisfy a number of the inmates' aspirations. Inmates were enjoined not to interfere in one another's business, not to 'lose their head,' not to exploit one another, not to weaken, and not to trust the guards. Like many another code, it was largely exhortatory, a form of 'figurative action' rather than a reliable predictor of behavior and its accompanying social relations generated neither 'a perfect solidarity … [nor] a warring aggregate' (Sykes, 1958, p. 83). In practice, some prisoners were forced or encouraged to service the sexual demands of others; some asserted their social standing by violence, defiance or conspicuous example; some supported illegal markets in the provision of goods; and overlapping hierarchies emerged.

The ensuing social order was ostensibly clandestine and based on a rejection of the rejecters, and the staff were supposed to suppress it, but the staff confronted their own difficulties. They themselves wielded great power in principle but little in effect, they were constrained by rules and the practical exigencies and limits of control, they were outnumbered, troubled by the precariousness of their authority, and discouraged from drawing their weapons lest they be disarmed by inmates. Their reply was to replace a formal equality of treatment by a *de facto* recognition and rewarding of the stronger inmates and inmate groupings, and they did so in exchange for a devolved social order in which inmates effectively regulated one another. The consequence was what Sykes called 'functional corruption,' but it could as readily be seen in functionalist language as a drift towards system integration, equilibrium, or homeostasis, an exemplification of the doctrine that the latent functions of action can work in seemingly paradoxical fashion to promote stability in social systems.

Goffman (1961) worked as a participant–observer in a mental hospital in Washington, DC, to construct a model of asylums, prisons, and like organizations as 'people-processing'

'total institutions' that were substantially cut off from the larger world by symbolic and physical boundaries; a continuous round of activity lived publicly within the walls; a relative lack of internal differentiation of space, role, and temporal schedule; an unbridgeable divide between staff and inmates; and, through what he called a 'mortification of the self,' the discarding of old identities and the assumption of new, degraded, and formally homogeneous identities peculiar only to the institution.

Five main processes have shaped the character and development of much of the work that followed. First has been the adoption of a somewhat critical stance. It was unavoidable that criminologists, penologists, and sociologists came motivated to the study of prison life, sometimes wishing to reform prisons, sometimes to abolish them, and sometimes – more rarely – to analyze them with the dispassion that they might extend to any other social institution. But it has been a strong distaste for prisons that has colored much of what they have written, and a number have been avowedly partisan and, indeed, polemical in their work. That stance has, in its turn, led to methodological difficulties in winning access to, and trust from, a number of key groups in prison, and prison officers especially.

Work has, second, selectively incorporated interpretations of transformations occurring in the political, administrative, and demographic conditions of penal institutions. In the United States, for instance, the sociology of prison life was born in descriptions of autocratic, *laissez-faire* regimes and the resistance that was waged by conservative inmates who feared they might lose power in the face of administrative reform. It moved on through a discussion of American penology's flirtation with rehabilitation in the early 1960s and the dilemmas that arose when the particularistic ethos of treatment confronted the universalism of disciplinary control. It looked at the radical politicization of prisoners, and particularly of black prisoners, in the late 1960s and early 1970s. It analyzed the efforts at legalistic reform, the organizational instabilities, fragmentation of inmate communities, and new waves of riots of the 1970s and early 1980s. And it has culminated most recently in an analysis of the new, racialized politics of mass incarceration and incapacitation that, in Simon's phrase, is the consequence of 'governing through crime' (Simon, 1993).

Internally, American prisons were to become 'Balkanized' into antagonistic racial camps based in some measure on a prior membership of street gangs. Externally, Simon has claimed, the logic of the penal system was to be extended out from the prisons through parole, policing, and probation to subject large blocks of the population, and particularly the young, black male population of the cities of the United States, to a tight control based on actuarial and risk-driven calculations of propensities to offend. Prison life has, in effect, spread beyond the walls of the American penitentiary to the ghetto.

Third, like the sociology of almost any other substantive area, the study of prison life has tended to edit and import some of the more general and evolving theoretical preoccupations of sociology at large as they have appeared to illuminate, and be illuminated by, those structural changes. It has already been observed, for instance, that work was launched inside a context set by the structural-functionalism and anomie theory of the 1940s and 1950s, a context suited to the study of willful, autocratic repression. Current work focuses on issues of resistance and authority, gender and power, 'governmentality' and 'structuration,' and other matters now engaging a number of the wings of sociology.

Fourth, like any other method, and aided by those transformations, interpretations and theoretical preoccupations, its focus has advanced restlessly from one phenomenon to another, continually introducing new 'facts' with which to re-interpret prison life. Above all, it has produced what is in effect a running series of footnotes or qualifications to the foundational models of the 1950s and 1960s.

It was easy enough at the beginning to overlook some of the finer and more nuanced details of structure. The social anthropologist in the American penologist would have been fascinated by the inmate community's vividly phrased argot and roles. What was less often reported – because it was less obtrusive and less interesting at first sight – was the presence of those who were relatively disengaged and played no part in the clandestine life of the prison, the 'retreatists' and others: who tried to serve their time uneventfully and discreetly and who eventually became interesting precisely because of their earlier neglect. What was also partially obscured at first was the lives of those apart from the inmate. Sociologists moved away from the inmate and towards chaplains, medical officers, and others: for example, the male prison officer beset by problems of violence, and the female prison officer and her gendering of control.

Studies report not only the features that were neglected in the earliest work, but also new features that have emerged since that work was done, but much remains unexplored, for instance, the structural repercussions of the social class of prisoners, aging and the age composition of prison populations, the world of prison administration, and such groupings as gay prisoners and the prison untouchables (the 'nonces' or nonsenses of English prison argot) imprisoned for sexual and violent offences against children or the elderly.

Most important, the political control of discreditable information and the absence of a sense of anthropological curiosity and of a robust ethnographic tradition in much of the world have ensured that there have been almost no studies of prison life outside Britain, North America and a few small pockets of northern Europe. Sociologists began to emphasize how the early models had tended to extrapolate from one form of time-bound regime alone, the American, authoritarian, maximum security prison for men. It is a model that works well enough where power is arbitrary and formally unchecked, controllers are outnumbered and resistance is fragmented, and it applies broadly to German concentration camps and Soviet labor camps as well as to some of the prisons of the United States. But doubts have been raised about how far or strictly it should otherwise be generalized. It is clearly a limited model. Take Ketchum (1965), who described how in Ruhleben, an internment prison camp established in Berlin for the citizens of countries hostile to Germany in the First World War, there could be seen almost none of the informal responses to incarceration listed by Clemmer, Goffman or Sykes. To the contrary: the inmate population behaved cooperatively, peacefully, and without mutual exploitation, and its conduct invites questions about the impact of class, shame, and pre-existing patterns of organization on the social construction of prison life.

Again, take research on a number of therapeutic or rehabilitative regimes outside the United States. Sparks (1994) studied Barlinnie, a small unit for long-term prisoners in a Scottish prison, and Genders and Player (1995) examined Grendon Underwood, an English therapeutic prison to which serving prisoners in other establishments could elect to go. The three authors declared that neither Barlinnie nor Grendon was critically troubled by the legitimation crises or conflicts of other prisons, but both institutions did benefit from being regimes within regimes – inmates could always be transferred back to the larger and more coercive system from which they had come – and it would be wrong to assume that therapy alone is a proof against disorder or confrontation. So it was that Mathieson's (1965) *Defences of the Weak* described a medium-secure Norwegian prison, organized on therapeutic lines, whose disunited and cynical inmates challenged those who guarded them in a language of 'censoriousness' that turned therapeutic ideology into a medium of criticism, defense, and attack. Theirs was a response very dissimilar to that of other models.

A second, allied form of qualification to the foundational model attacked the proposition that prisons are total institutions which sever biographies and create new men and women within an indigenous culture (Sparks et al., 1996, p. 44). Instead of the fractured identities described by Goffman, study after study has revealed that inmates actually bring with them beliefs, associations, and styles of behavior from the outer world.

The importation into prison of social forms from the street gangs and antagonistic racial politics of America has already been noted, and there are other borrowings that have presumably been colored by local and national traits in the world outside the walls. Thus, Irwin and Cressey (1962) talked in America of *thieves* who carried a wider criminal culture into prisons, treating imprisonment as a career contingency; *convicts* whose behavior was a localized adaptation to the special travails of prison life; and *square Johns* who had an allegiance to neither convict nor thief but to a show of obedience to authority. Also, Cohen and Taylor (1972) talked about the affinities between the manner in which long-term inmates in Durham Prison in England managed problems of serving time and the offenses for which they had been convicted, armed robbers worrying about physical deterioration and concentrating on body-building exercises, and fraudsters engaging in copious attempts at litigation.

The discovery of the gendered character of imprisonment is as revealing. The very first studies dwelt on institutions for men. Whilst it was recognized from the outset that male inmates confronted largely male problems stemming from a loss of liberty, status, and heterosexual contact, gender itself was not treated as especially problematic or interesting. It was only when ideas about sexual identity were applied in explanations of the behavior of women inmates in the 1960s, women who were said to form themselves into pseudo-families in response to a loss of emotional sustenance, that the influence of gender itself became notable. Other sociologists have subsequently exextended and modified that early work, but the thesis that women combine together differently remains. Later, ideas about masculinity were themselves turned back on the social organization of men's prisons to translate them into places ordered by a 'hegemonic masculinity.' Male prisons, it was argued, must be understood as institutions that are dominated by a very masculine exercise of violence, reliance on hierarchy, ritualized combativeness, and the suppression of displays of emotion and vulnerability.

Last, it must be stressed how closely, although never absolutely, the study of prison life has been bound up with the use of ethnographic methods (Terence and Pauline Morris said of their base in Pentonville Prison, London, that it was 'like the anthropologist's hut on the village street' (Morris and Morris, 1966, p. 8)). Its history has, by extension, roughly paralleled the rise and fall of sociological ethnography itself. It was probably at its most vigorous between the 1950s and early 1970s, when, according to Janowitz, it 'contain[ed] some of the most outstanding research monographs in sociology' (Foreword to Jacobs, 1977, p. ix). Its decline may be linked in part to the seemingly inevitable half-life enjoyed by any body of theory and research, and to problems of access and publication that began to surface in the 1970s when prisons were turbulent and their managers became politically defensive and defeatist. But it may also be attributed to the ascent to influence of Michel Foucault (1979), whose political economy of discipline prompted scholars to turn *en bloc* to reflections about what they called 'penality' in a markedly more abstract and empirically disengaged manner.

Foucault took Bentham's plans for a concentric, panopticon prison to be an especially telling representation of the new technologies of control that were emerging in society at large. Prisoners in the brightly lit rim could never know whether they were being observed by guards in the shadowy inspection tower at the center, and the result was supposed to be that they would discipline themselves, colluding in their own subordination in a decentralized, self-sustaining, economical and dispersed system of power. The panopticon was never finally constructed in England, and Foucault's history was flawed, but so seductive and wide-reaching was his metaphor that it became an archetype for a large new family of ideas, and sociologists came to adopt Foucault rather than Clemmer, Sykes or Goffman as their mentor. Jonathan Simon (1999, p. 4) observed that, 'the great tradition of studies of prison social organization that begins with Clemmer and Sykes … has largely ceased in the last twenty years … Much of the research now is conducted from afar [and] … the new distance introduces important interpretive problems … .'

Editor's Note

The study of life behind bars has continued to evolve since the original publication of this article, of course. A flavor for recent developments from a variety of methodological, disciplinary and geographical perspectives can be obtained from the following: Alison Liebling et al. (2012), Dominique Moran (2013), Yvonne Jewkes (2012), Meredith Huey Dye et al. (2014), Crewe (2011), and Rod Earle and Coretta Phillips (2012).

Abstract

Prison life both fascinates and repels. As with many aspects of punishment, it attracts the interest of both academics and the general public. In this short and accessible article, the principal issues of prison life are presented in a historical context that traces the emergence of focused academic study of the way people live, and die, in prison. The most influential theoretical perspectives are clearly set out alongside a discussion of their influence on research and analysis in the UK and beyond. Questions of women's experience and that of black and minority ethnic prisoners are explored before a consideration of postcolonial prison studies is introduced. These studies of prison life beyond the axis of Europe and North America challenge some of the accumulated academic wisdom of Anglophone and European studies of prison life, indicating the potential of novel developments to come in an era which, unfortunately, shows no signs of declining to produce more and more prisons.

The sociology of prison life, briefly defined, encompasses the systematic study of prisoner societies, prison staff culture, and/or prisons as organizations. With continued and increasing uses of the prison as a criminal justice disposal, academic interest in prison life has been sustained and has grown across many countries across the globe. Contemporary studies of prison life form a diverse body of work that variously examine the prison world through concepts of space, place, architecture, gender, ethnicity, law, political economy, and national and global governance. Contemporary developments within the sociology of prison life, however, continue to build upon and extend a knowledge base that has developed cumulatively since 1940 and thus the first academic sociological study of prison life.

Foundations

In *The Prison Community* (1940), Donald Clemmer presented the first sociological study of prison life. Based on his research in the Menard Branch of the Illinois State Penitentiary, Clemmer put forward and established the notion of 'prisonization.' This concept can be understood as the impact of the prison experience on prisoners, and is thus a descriptor of the process by which those who enter prison take on the "folkways, mores, customs, and general culture of the penitentiary" (1940: 299). Clemmer argued that prisonization may occur to greater or lesser degrees depending on a range of factors (length of sentence, level of association with peer groups within prison, strength of ties outside prison, inter alia). Some of the factors associated with the process result from the peculiarities and constraints of the prison environment, including the acceptance (or resistance) to the powerless position of being a prisoner and the conditions under which prisoners must eat, dress, work, sleep, and so forth. However, Clemmer suggested that relational factors also influenced the process. Chief among them was the extent to which a prisoner integrated into a primary group among the prisoner community. Belonging to a primary group required adherence to an 'inmate code' or system of norms that demanded loyalty to the prisoner group and opposition to staff. The result of the process, according to Clemmer, was a (further) rejection of societal norms and a continued or deepened commitment to a value system outside the laws and conventions of mainstream society. Clemmer's findings and theories about prison life and prisoner experience dominated academic understandings and thinking about the prison for over 20 years and, to some extent, his ideas remain influential even today.

In the late 1950s and early 1960s, further studies of the prison began to emerge. Three further early sociological studies of the prison are worthy of note. In 1958, Gresham Sykes published *The Society of Captives: A Study of a Maximum Security Prison*, based on research in the New Jersey State prison. In this work and in Sykes and Messinger (1960), aspects of the 'inmate code' and its influence on prison social life and prisoner experience are examined. Sykes and Messinger argued that Clemmer's theory of prisonization was incomplete because it did not explain how or why prisoner culture formed in the first place. Sykes argued that the prison environment exerted pressures or 'pains' that altered the relational parameters between prisoners. Thus, prisoners needed to adapt to various demands of the environment and their fellow inmates in order to endure the ordeal of prison life. The pains of imprisonment, Sykes argued, included several deprivations: liberty, goods and services, heterosexual relationships, autonomy, and security. These deprivations, in turn, exercised a destabilizing influence that could result in competing prisoner hierarchies, clandestine activities and illegal markets, and a variety of other informal structures and *sub rosa* codes of conduct.

Around the same time as Sykes' study of the prisoner society, another alternative consideration of the experience of institutional confinement was put forward. Drawing on a participant-observation study of a mental hospital in Washington, DC, Chicago School sociologist, Erving Goffman published *Asylums* in 1961. Goffman coined the term 'total institution,' which he defined as institutions that have an

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45035-X

"encompassing or total character, [as] symbolised by the barrier to social intercourse with the outside … that is often built right into the physical plant, such as locked doors, high walls, barbed wire … The central feature of total institutions can be described as a breakdown of the barriers ordinarily separating [the] three spheres of life [sleep, play and work]" (1961: 16–18). Goffman utilized a symbolic interactionist (or interpretivist) approach to consider the experience of confinement and argued that through the inherently artificial and degrading environment of the total institution, inmates experience a 'mortification of the self.' Their previous identities become disrupted or jettisoned, and new institutional identities take shape. However, these new identities form in response and are peculiar to the particular institution in which the inmate is confined. The struggle to cope with and maintain a sense of identity in the face of staff and institutional pressures to erode the prisoner's sense of self were identified by Goffman as the main interactional dynamics that characterize total institutions.

In 1962, John Irwin and Donald Cressey published an important theoretical article entitled: *Thieves, Convicts and the Inmate Culture*. In this paper, they argued that too much emphasis had been placed on the influence of the prison environment on the development of inmate culture, and that not enough attention had been focused on the external cultural influences and behavioral patterns of prisoners. Irwin and Cressey argued that prisoners 'imported' certain subcultural values, beliefs, and conventions into the prison world that had held meaning for them outside. Irwin and Cressey's paper was the first to consider the social roles that prisoners occupied prior to their imprisonment and the extent to which this 'latent culture' influenced in-prison culture. They suggested that the prisoner community corresponded directly with current and changing societal trends and that prisoner societies were more chaotic, diverse, and less rule-bound than previous studies had suggested.

Dominant Theoretical Models

The main theoretical models on prison social life that have dominated and, to some extent, continue to feature in the research literature have their origins in the above mentioned foundational studies. Thus, theories on the sociology of prison life tend to be based on either a functionalist model, an 'importation' model, or some integrated version of these two broad approaches.

Functionalist models take a problem-solving view to account for prisoner culture. From a functionalist perspective, it is thought that prisoner culture develops as it does *in response or as an adaptation to* the frustrations and deprivations of imprisonment. The purest branch of the functionalist model argues that any differences in the organization of prison establishments are irrelevant because the experience of total institutions is so coercive that it homogenizes prisoner responses to their environment (see Clemmer, 1940; Sykes, 1958; Goffman, 1961). By contrast, a situational functionalist model argues that prisoners' responses to prison life are situationally contingent on institutional characteristics (Grusky, 1959; Wilson, 1968). Broadly speaking, functionalist perspectives are known in the prison literature as 'deprivation' models because they seek to explain prison life and prisoners' adaptations to it as responses to the pains of imprisonment and the deprivations associated with the loss of liberty.

In response and in contrast to functionalist perspectives, explanations that favor an importation model argue for the importance of preprison social roles in shaping prisoner culture. Importation models are underpinned by a 'negative selection' view of the prisoner group. That is, involvement in criminal activity is the one common variable among prisoners, which is indicative of varying degrees of opposition to conventional norms. Thus, the social environment of prison life is shaped not only by the constraints of the prison environment, but also by the imported value systems, customs, and the various subcultures to which prisoners belong prior to their entry into prison.

Further studies of prison life have proposed slight deviations from these models. For example, Jacobs (1977), DiIulio (1987), and Useem and Kimball (1989) identified the importance of administrative approaches, organization, and control on influencing the prisoner society. However, much contemporary prison literature tends to present integrated versions of prison social life, which draw on aspects of both importation and deprivation models (Tittle, 1972; Liebling and Arnold, 2004; Crewe, 2009).

Mainstream Studies of Prisons and Prison Life in the UK

Subsequent to the above foundational studies, a number of in-depth examinations of the prison have been undertaken in a variety of penal setting, many emerging from within the UK (for example, inter alia Morris and Morris, 1963; King and Elliott, 1977; Carlen, 1983; Sparks et al., 1996; Liebling and Arnold, 2004; Crewe, 2009). The first sociological study of prison life in Britain was conducted by Terence and Pauline Morris in Pentonville prison in 1963. Their research provided a great deal of descriptive, ethnographic detail about Pentonville and drew comparisons to the work of Clemmer and Sykes. However, among prison administrators, the work was received as a polemical reading of the prison and was thus viewed as a somewhat controversial contribution to the prison literature.

Since the 1960s, a steady stream of sociological commentary, research, and scholarship on prisons in the UK has emerged from the Institute of Criminology, University of Cambridge. Initially, the relationship between the Institute of Criminology and prison administrators was forged by the first director of the Institute, Sir Leon Radzinowicz. Radzinowicz acted as a frequent advisor to senior civil servants and prison administrators, and also sat on the Advisory Council on the Penal System (1966–78). Through this council, Radzinowicz advised on a number of matters associated with penal and prison policy, including chairing the committee, which set up the system of maximum-security prisons in England and Wales (known as the 'dispersal' prison system, see Radzinowicz, 1998).

The Institute of Criminology has continued to work closely with prison administrators in the UK and elsewhere, specializing in sociological studies of the prison. In 1996, Richard Sparks, Anthony Bottoms, and Will Hay published *Prisons and*

the Problem of Order. This book, based on ethnographic research in two maximum-security prisons (Albany and Long Lartin) in the late 1980s, considered the factors that influenced the orderliness (or otherwise) of a prison regime. Sparks et al. argued for the importance of legitimacy in the administration of prisons. Although a significant sociological study of prison order and administration, this work is better described as an examination of prisons as organizations, rather than a study of prison life per se. Thus it might be differentiated from other works in prison sociology, which focused more directly on prisoner societies and social roles.

In 2000, the Prisons Research Centre at the Institute of Criminology, University of Cambridge, was established under the directorship of Professor Alison Liebling. Liebling has established a formidable reputation as an authority on prison quality of life, having conducted several large studies on various aspects of prison life, including prisoner suicide, self-harm, and safer custody (1992; Liebling et al., 2005), staff–prisoner relations (2011), the 'moral performance of prisons' (Liebling and Arnold, 2004), inter alia. Liebling's work on 'what matters' in prisons has been influential in shaping the way prison administrators measure and conceptualize prison quality. Liebling's concept of 'moral performance' draws administrative attention to several aspects of humane custody, such as respect, trust, safety, dignity, and well-being. In addition to Liebling's own work, a steady stream of researchers and doctoral students working at the Prisons Research Centre have produced numerous sociological and psychosocial studies of prison life, prisons as organizations, and prison administration (e.g., Bosworth, 1999; Crewe, 2009; Drake, 2012).

Consideration of Differing Perspectives

One of the main difficulties faced by sociological prison researchers and theorists concerned with examining the inner life of prisons has been untangling the complex relationships that influence it. As with society in general, there is an extreme complexity of attitudes, opinions, beliefs, and values of any given prison population. Although many studies of the prison have ignored the diversity of prisoner experiences and the heterogeneity of prisoners' viewpoints on their own lives and their reflections on the experience of imprisonment, there have been some valuable contributions that have applied interpretive sociological theory to ethnographic or interview data. These works have illustrated the connections between human agency, intersubjective meanings, and environmental or structural conditions of prison life (see Goffman, 1961; Irwin and Cressey, 1962; Cohen and Taylor, 1972; Bosworth, 1999; Jones and Schmidt, 2000; Rowe, 2011). There are, however, a range of structural positions or standpoints from which prison life might be considered, including the perspective of women prisoners, LGBT prisoners, black and binority ethnic prisoners, or civilian versus disciplined prison staff.

Sociology of Prison Life in Women's Prisons

Like many areas of sociology, understandings of the human experience of prison life were initially androcentric, i.e., established from the standpoint of men's experiences. Though there are some very early examinations of women's imprisonment from a sociological perspective (see for example Selling, 1931), the first large-scale studies of women's imprisonment were conducted in the mid-1960s by David Ward and Gene Kassebaum (1965) in California and Rose Giallombardo (1966) in West Virginia (but see also Heffernan, 1972). These early studies did not fully examine women's prisons or women's experiences of imprisonment as separate areas of inquiry from men's prisons. Instead, the findings from studies of prisoner societies made up of women were compared and contrasted with previous findings from studies of men in prison. Ward and Kassemaum, for example, commented on how women's experiences of imprisonment differed noticeably from men's, that there was not a strong 'inmate code' among women. They argued that women prisoners tended to form 'families' or 'cliques' through which contraband might be distributed and shared, rather than the entrepreneurial, black market that characterized men's imprisonment. These early researchers argued that women's gender roles were imported into the prison with them, while the deprivations and context of institutional life shaped and dictated the way these roles were fulfilled. As Candace Kruttschnitt and Rosemary Gartner (2005: 22) have noted "Important sources of variation in adjustment – institutional characteristics and characteristics of the prisoner population – were left largely unexplored."

A great deal of the sociology of women's imprisonment has focused on women's intimate relationships in prison (Norris, 1974; Propper, 1981; Owen, 1998). However, more recent developments in the sociological literature on prison life in women's prisons has moved on to consider a range of other aspects of women's imprisonment, including the way women are constituted in penal discourse and are subjected to a gendered form of control (Carlen, 1983); how experiences of imprisonment are shaped by characteristics of the institution (Rock, 1996); the influence of macro-sociological and political factors on women's experiences of imprisonment (Kruttschnitt and Gartner, 2005); and the way women construct identities, engage in resistance, and negotiate power in prison (Bosworth, 1999; Rowe, 2011).

Convict Criminology

Much insight has been gained into prison experiences from 'insider' perspectives, including autobiographical and fictionalized accounts from authors with experience of incarceration (e.g., Serge, 1930; Davis, 1971). In particular, the work of 'convict criminologists' (those who have experienced prison life first hand, as prisoners, and who now have academic careers) has provided the sociology of prison life with vivid and reflective accounts of prison life, and studies of prison that could not have been provided from a conventional perspective. Convict criminology is a branch of critical criminology started in the late 1990s by academics in the USA who were prisoners, exprisoners, or exprison staff. It is concerned with challenging existing definitions of crime, the overuse of prison as a penal sanction, and exposing the shortcomings of the criminal justice system. Convict criminology emerged in the USA as a response to the continued failure of mainstream criminologists and criminal justice practitioners to appreciate the perspective of the convict. This failure, according to convict criminology, is

evidenced in the persistent representation of prisoners and exprisoners as distinctive, 'inferior' types of human being. These perceptions foster a damaging indifference toward a proliferating and self-sustaining criminal justice industry that is both inhumane and unnecessary (see in the USA, Irwin, 1970; Jones et al., 2009; in the UK Aresti 2012; Earle, 2011).

Black and Minority Ethnic Prisoners

That prisons tend to gather the kinds of people that Loic Wacquant (2001) describes as 'the wretched of the city' is no particular revelation to anyone with even the most passing familiarity with who gets sent to prison. However, any visitor to a US or British prison will be quickly confronted by visual evidence that this is a dark-skinned population. Much more than in the general population, prisoners tend to be drawn from black and minority ethnic groups. White people are still a majority in these country's prisons, but their chances of being incarcerated are far less than their black or minority ethnic counterparts. In the USA, analysts such as Angela Davis (2003) and Michelle Alexander (2010) identify the continuities of American racism that translate from the days of slavery, the plantation system, through the legal machinations of 'Jim Crow' to the current 'prison-industrial' complex.

Loic Wacquant (2001) recognizes the interplay of race and class dynamics in the declining American cityscapes as generating 'a deadly symbiosis' in which black ghettos feed the prisons, who in turn recycle their damaged black populations back into the decrepit housing and grinding poverty that produced them in the first place. Controversially, Wacquant describes this relationship as entirely functional to a largely white neoliberal political class as it serves to separate and distinguish a black 'underclass,' reproducing white anxiety and simultaneously offering containment of its racialized threat.

Few other white commentators provide such an urgent or powerful analysis of the racial configurations of the US penal nightmare. His analysis is rich in detail, broad in sweep, and grand in gesture. However critics (Newburn, 2010) find a tendency to erase differences and variation within the US carceral complex that do not align so closely with the racialized dynamics he identifies.

The variable and shifting dynamics of race, the state, and prison on the opposite side of the Atlantic are examined in a detailed British empirical study (Phillips, 2012). Coretta Phillips' study is invaluable in analyzing the specific configurations of 'the multicultural prison.' Phillips finds 'enduring trialities' in the combination of race, class, and gender that provide the two prisons she studied with a diverse population. Attending to the detailed stories gathered through sustained ethnographic immersion, she provides a nuanced account that engages as fully with the 'pains of racism' as it does with the pains of incarceration. In place of simplistic dyads of race, Phillips (2012: 203) presents 'the contorted inflections of racism.' Amid the continuing evidence of systemic, institutionalized racism that selects and sieves the black and minority ethnic population through every stage of criminal justice procedure from arrest through to incarceration, Phillips also identifies changing patterns of resistance, reconciliation, resentment, and racialization. The multicultural prison reflects multicultural realities in being both convivial and conflicted.

The global diversity of prison has distinctive patterns of racialization, but the sheer scale and longevity of the disproportionality in the US and British prison systems demand focused attention. Determining the precise mechanisms that produce such features of prison populations is a complex task and neglecting to do so seems to be implicated in their endurance.

Prison Studies Grounded in Sociological Critique

Considerations of prison life that have focused heavily on either administrative concerns or the factors that account for differing prisoner societies have tended to avoid questions associated with the broader social meaning of imprisonment as a form of punishment or the extent to which prisoner experiences serve the assumed purposes of imprisonment. However, there is much sociological and critical criminological literature that problematizes the use, operation, and proliferation of prisons. In 1972, Stanley Cohen and Laurie Taylor published *Psychological Survival: The Experience of Long Term Imprisonment*. This book considers the lived experience of a maximum-security wing of a prison in the North of England. It exposes the personal and psychological struggles of prisoners attempting to cope with isolation, heavy control measures, and long-term prison sentences. The book is one of the first to offer an account of prison life from the standpoint of prisoners. Cohen and Taylor achieved a degree of authenticity that had eluded previous prison researchers by developing their ideas for the book in collaboration with the prisoners who they met through a teaching-based relationship, rather than during a formalized research project per se. The book continues to influence critical prison scholars due to its poignancy in capturing and analyzing aspects of the experience of long-term imprisonment.

A number of critical studies and writings about prison life have aimed to draw attention to the chronic failure of prisons or to question the extent to which experiences of imprisonment fulfill the supposed or official purposes of prisons as a social institution. For example, British prisons in the 1970s and 1980s were troubled by prisoner riots and disturbances, thus critical scholars were particularly concerned by these problems. In 1991, Phil Scraton, Joe Sim, and Paula Skidmore published *Prisons Under Protest* (1991), which examined the problem of prison protests through the study of Peterhead prison in Scotland. The book argued, unequivocally, that any appearance of order in prisons was purely the result of enforced compliance or coercion and that "Life in most British prisons is an unrelenting imposition of authority" (1991: 62). Moreover, one of the most influential critical studies of the prison is found in Thomas Mathiesen's *Prison on Trial: A Critical Assessment* (1990). In this volume, Mathiesen systematically outlines the many ways in which prisons fail to fulfill their supposed purposes (e.g., deterrence, preventing reoffending, etc). He declares the prison a fiasco, but exposes some of the underlying structural and political economic forces that perpetuate its use.

Similarly, radical sociological writing and activism against the use of the prison has a long history in the USA. Angela Y. Davis has perhaps been the most vocal opponent of the use of the prison in the USA and the expansion of the 'prison industrial complex.' The prison industrial complex is a term

grounded in political economic analysis of the prison system represents the idea that the expansion of the prison population is attributable to the political and economic influence of both private prison companies and the various ancillary agencies and corporations that supply goods and services to maintain the prison system. Davis has thus drawn academic and public attention to some of the structural social factors that influence the use of the prison (and, in turn, prison life), including the problem of the disproportionate use of imprisonment for people of color.

Prison Life Beyond the North

We have seen that the dominant theoretical models in the sociology of prison life literature were developed mostly in the light of situated practices in just two countries, the US and the UK. With the expansion of the use of the prison around the world, however, historical, ethnographic, and first-hand examinations of prison life outside of Anglo and Northern societies have recently begun to emerge, much in the English language (see, inter alia, Aguirre, 2005; Bandyopadhyay, 2010; Dikötter and Brown, 2007; Piacentini, 2004; Focaal, 2014; Miller and Campbell, 2014; Prison Service Journal, 2014; Salvatore and Aguirre, 1996). An essential starting point for this literature is that Southern prisons are poorly resourced in comparison to the prisons of Western Europe and North America. Important for current purposes, Southern prisons are not only more overcrowded and austere than prisons in the US and the UK, for example, but also they are often characterized by acute staff shortages. In Brazil, for instance, it is quite normal to find just one guard on duty per 100, even 200 inmates (Darke, 2013). Under these conditions, officers depend on inmates to collaborate in the administration of everyday prison routines, for instance, working as office clerks, medical auxiliaries, cleaners, cooks, and porters, and on inmates' families and voluntary sector groups to provide essential goods and services such as food, toiletries, medicines, and doctors. Equally significant, in many countries prison officers only enter the wings to lock and unlock cells. As a result, Southern prisoners are largely left to their own devices, not only to organize everyday routines on the wings, but also to maintain discipline (Darke and Karam, forthcoming; Garces et al., 2013).

This recent vibrancy in academic engagement with prisons in the postcolonial world raises significant questions over the extent to which the dominant theoretical models in the sociology of prison life literature (regarding prisonization, mortification, latent culture, and prisons as organizations) that we outlined earlier in this article are applicable beyond the global North. For instance, despite the obvious material deprivations and inability of officers to provide security, researchers have noted that Southern prisons are not necessarily as disorderly or inmate hierarchies as competing and predatory as our theories might predict. To make sense of this apparent contradiction, studies of Southern prison have focused on the ways in which prison staff and inmates may respond to the inhumane conditions in which they find themselves living and working through negotiation rather than conflict. Mahuya Bandyopadhyay (2010) explains that bad prison conditions give rise to social bonds as well as social tensions. When deprivation becomes a shared experience, as it is in prisons across the global South, it appears that humans have a natural capacity for solidarity and mutual aid.

Finally, and closely related, the impoverished nature of postcolonial prisons leads to a need to reconsider the universal applicability of Goffman's (1961) concept of the total institution. The first point that needs to be made here is that the barriers between prisons and communities are generally more permeable than in the West. For instance, prisoners typically have greater contact with their families, who we have noted, are often relied upon to make up for shortfalls in state provision. Further, with the growing phenomena of gang culture in the guardless prison wings and the likewise inadequately policed ghettoes of Latin America and other parts of the developing world (Hinton and Newburn, 2008), prison and community life are becoming increasingly linked. For instance, in large parts of Brazil, prisoners are allocated to particular prisons and prison wings according to the gang in control of the area that they come from. Involvement in gang activity itself is not a requirement. Outside the prison, gangs provide material support such as food parcels to prisoners' families. Gang leaders arriving in prison are likely to be fast-tracked as inmate leaders; imprisoned gang leaders are likely to return to positions of authority in the community upon release.

The work of prison researchers beyond the West casts new light on the sociology of imprisonment. The enduring thematic issues associated with prison life, such as order, security, control, and staff–prisoner relationships, take on a different character, offering new insights when examined in differing cultural, social, and political contexts. Christie (2004) has argued that prisons expose key aspects of the machinery of the states that they represent. Thus, by considering prisons from different social and political contexts alongside one another, there is much understanding to be gained both about practices of imprisonment and the constitution of state powers. As the use of the prison continues to proliferate around the world, findings and observations from sociological prison studies from all corners of the globe will form a vital part of the continuing development of our understanding of the sociology of prison life.

Abstract

The Prisoner's Dilemma (PD) is a game whose Nash equilibrium is not Pareto efficient. The sheer perversity of the interaction involved in the PD has bewildered game theorists and social scientists alike. Despite the fact that players could be better off by jointly cooperating, they have individually a dominant strategy for defection that carries out a suboptimal outcome for everyone. This article explores and assesses this result, contrasting one-shot and repeated interactions.

Introduction

The Prisoner's Dilemma (henceforth, 'PD') figures prominently in game theoretic literature. It was first devised and discussed by Merrill Flood and Melvin Dresher in 1950, in the context of studies pursued by the RAND Corporation on strategic interaction (see Poundstone, 1992). Princeton mathematician Albert Tucker is responsible for the story usually related to introduce the PD; it appeared in print for the first time in Luce and Raiffa (1957). One possible version of it recounts how two criminals are arrested and placed in isolated cells. Each of them only cares about his own personal welfare, and not about the well-being of his accomplice; they both wish to minimize the number of years they remain in jail. The sheriff talks to them separately and offers the following proposal: "You can confess or remain silent. If both of you confess, you will get 10 years in jail. If you confess and your accomplice remains silent, you will get a one-year jail sentence and your accomplice will remain in prison for 25 years. If both of you remain silent, you and your accomplice will be jailed for 3 years."

Given the sheriff's proposal, each prisoner can reason thus: "If my partner remains silent, it is better for me to confess, because one-year in jail is better than three. If my partner does confess, it is also better for me to confess, because 10 years in jail is better than 25. In either case, irrespective of what my accomplice does, it is better for me to confess than to remain silent." Both players reason the same way, and they get 10 years each. The surprising result is that they could have obtained a mutually beneficial sentence of 3 years, had they both remained silent.

The PD has acquired a pervasive importance in mainstream social sciences and has been the subject of innumerable articles and books. Phenomena as diverse as the provision of public goods, the overexploitation of natural resources, the existence of price wars between firms, the escalation in arms races between superpowers and the overexpenditure in political party campaigns have been employed as putative candidates for analysis in terms of a PD. A note of precaution must be raised at this stage. Social phenomena are very rich. Game theoretic modeling requires impoverishing reality to focus only on a few abstract parameters, so it is never obvious whether a certain real-world situation satisfies the mathematical structure of a PD. We need to be careful not to confuse the target phenomenon with its game theoretic *representation*. Further discussion is given in Section From Social Phenomena to Game Theory.

The following section analyzes the structure of a two-person PD that is played just once; Section *N*-Persons PD addresses the problems that arise when we consider extending the two-person case to a game with *n*-players; Section Iterated PD, Two Persons deals with iterated versions of the game; and Section Evolutionary PD examines the so-called evolutionary PDs.

Two-Person, One-Shot PD

Figure 1 models the PD. Payoffs are represented by cardinal numbers. To keep it simple, assume that the years of imprisonment linearly amount to negative units of utility. Assume our prisoners are 'Row' and 'Column,' respectively. Each of them has to choose between options C and D, where C (the 'cooperative' choice) is the option to remain silent, while D ('defection') amounts to confession.

Information on Figure 1 can be generalized. For a PD matrix to arise it is sufficient to have payoffs a, b, c, and d for Row, and payoffs a^*, b^*, c^*, and d^* for Column, as shown in Figure 2, such that $c > a > d > b$, and $c^* > a^* > d^* > b^*$, with both $a > (c + b)/2$ and $a^* > (c^* + b^*)/2$ (Rapoport and Chammah, 1965; Axelrod, 1984). If ties are allowed the strict inequality could be relaxed by either $c \geq a$ or $d \geq b$, but not both; the same considerations apply to Column's values. If Row and

Figure 2

Column have the same values, the matrix is said to be symmetric (as in Figure 1).

Mainstream game theory usually assumes, for any game, that players have common knowledge of their options and payoffs, as well as of the fact that they are rational – meaning, not only does each player know that they are both rational, but each player also knows that the other player knows that they are both rational; each player knows that the other player knows that she knows this, etc. Note, however, that common knowledge of rationality is not necessary to account for the prisoners' reasoning as mentioned in Section Introduction. Each player has a strictly dominant strategy (D), and hence the game has a unique Nash equilibrium (D, D); if ties are allowed, D is weakly dominant for each agent. In either case, given that defection dominates cooperation, standard game theory has it that players can solve the game by just looking into their own payoffs and ignoring the payoffs of their opponent; the players cannot do better by unilaterally departing from their dominant strategy (but see Rationality Considerations for attempts to question the use of dominance reasoning in this or similar settings).

Still, insofar as both $a > (c + b)/2$ and $a^* > (c^* + b^*)/2$ hold, the pair of strategies (C, C) is the only Pareto-optimal point of the game, and hence both agents will be worse off by following the dominant strategy. (By contrast, if the inequalities are not satisfied, the agents will be able to reach Pareto-optimal points by using independent mixed strategies – hence, the injunction to defect might not be perceived as perplexing as in a bona fide PD.) The most interesting feature of the PD then is the existence of a unique Nash equilibrium (D, D) that is Pareto suboptimal. The explanation of why the players end up with a Pareto-inferior outcome is not hard to grasp. As a matter of fact, each player distinguishes between what is and what is not under his control. Row player compares payoffs along Columns – the only variables that are open to him – and Column player compares payoffs along Rows, for the same reason. By contrast, nobody compares payoffs along the diagonal, because diagonal payoffs are not under the *exclusive* control of any of the two players.

It has been argued that a PD models, with disarming simplicity, a possible conflict between individual and collective rationality. Collectively, everyone would be better off cooperating than defecting, but, individually, defection is the dominant strategy for each player. Incidentally, notice that the putative conflict between individual and collective rationality need not be read as a clash between egoistic and altruistic motives. Two agents can have altruistic preferences and yet be in a PD. By way of illustration, suppose Row and Column are placed in separate rooms and are given the option to press either a C-button or a D-button. They both know that, if Row presses the D-button while Column presses the C-button, \$4 will accrue to Column and nothing to Row; *mutatis mutandis* for Column pressing the D-button while Row presses the C-button. If they both go for the D-button, they receive \$1 each; if they both go for the C-button, they both get \$3. Suppose each agent only cares about the well-being of his partner; to simplify things, assume that Row obtains one unit of utility for each dollar received by Column and vice versa. The situation can then be described by the matrix shown in Figure 3, which is just a special case of Figure 2, and thus it has the structure of a PD, despite the fact that both agents have altruistic motivation.

As we have indicated, standard game theoretic rationality excludes the possibility of cooperation in a canonical, one-shot PD; the structure of interaction is such that only defection is sanctioned as rational. Of course one can always seek to modify the matrix in order to make defection more costly, for instance by introducing punishment (see Section From Social Phenomena to Game Theory). But this move should be carefully interpreted. The payoffs are supposed to factor every relevant information; they already include all there is to consider, and not just visible compensations such as money or years of imprisonment. Therefore, if the payoffs are changed, quite simply the game is changed. Once that happens, there is no point in claiming to have found a cooperative solution to the PD, because the game that is being played is not a PD any more (Binmore, 1994).

At this stage, it is crucial to distinguish between a PD *matrix* and a PD *situation*. The PD matrix is a mathematical structure. The PD situation is simply the target phenomenon that one wishes to model. In the following subsection, we elaborate on the significance of this distinction. We shall examine three different ways in which agents facing the very same scenario might avoid the fate of a PD: they can try to change the circumstances, so as to end up with a game defined by a less problematic matrix; they can understand the circumstances differently (or equivalently, they can seek to change their preferences) in order to become involved in a more benign game; or they can refuse to conceive themselves as playing a game in the first place, among other possibilities.

From Social Phenomena to Game Theory

Once the players believe they are dealing with a PD situation, they can attempt to modify their incentives so as to promote cooperation. The presence of third-party punishers, for example, helps to mitigate defection by forcing players to enter

		Column	
		C	D
Row	C	3, 3	0, 4
	D	4, 0	1, 1

Figure 3

into mutually advantageous exchanges. Legislation, for instance, is devised to enable people to cooperate by converting PD situations into interactions with cooperative solutions. Note that this leaves what we have stated concerning the logic for defection in the original PD *matrix* completely intact.

External intervention is not the only way a PD situation can be modified. Cooperation can be generated *endogenously*. By way of illustration, consider Oliver Williamson's analysis of trade practices during the Middle Ages, between merchants located in distant places (Williamson, 1983). The lack of an enforcing mechanism posed a serious problem of credibility at the moment of exchanging commercial promises. Both merchants would be better off if they could cooperate; but they were both afraid of the opportunistic behavior of the other party; they preferred not to cooperate rather than cooperate without being reciprocated. The solution was to allow for the exchange of asymmetrically valued goods. One merchant would send his own son to the other merchant to add credibility to his promise of future payment; the other would send the merchandise; once payment became effective by the first merchant, the second would proceed to liberate the son who was retained as credit security. This mechanism endogenously circumvents a situation of mutual distrust which could lead to a PD matrix, but without assuming exogenous agents charged to enforce contractual agreements.

Such examples of both exogenous and endogenous mechanisms being used to enhance cooperation can be described as cases in which agents find themselves in a PD situation, but where a PD matrix is nonetheless avoided due to changes in the relevant circumstances. Even more radically, notice that different agents under the same circumstances can disagree on whether they are, or are not, involved in a PD situation. Clearly, if the agents do not consider themselves as dealing with a PD situation, they will just not have a PD matrix to worry about; in general, matrices are obviously underdetermined by real-world phenomena. We can call it *the problem of interpretation*: whether players are or are not trapped in a dilemma depends on the way they interpret the relevant facts and on how they structure their preferences.

Thus, rational agents can use game theoretic considerations to arrive at quite different conclusions. Consider a modified version of Tucker's story; the sheriff's proposal remains as before (so in a sense, the external facts have not changed), but both prisoners attribute great value to cooperation in itself. Suppose their utilities are as shown in Figure 4.

Then the rankings from Figure 2 no longer hold; rather, we now have $a > c \geq b > d$; Column values are symmetric. We have just obtained what is often referred to as a *Stag Hunt* game. It is paradigmatically illustrated with the story of two friends who go on a hunt; they can choose to hunt either a stag or a hare, and neither knows what the other will choose to do. In order for Row to succeed in hunting a stag, Column must choose to hunt a stag too. Furthermore, each of them can hunt a hare without help, although a hare is not as worthy as a stag. Notice that here we have two Nash equilibria, (C, C) and (D, D), though of course only (C, C) is Pareto-optimal. It is a 'game of trust,' or a 'game of assurance': if Row has great confidence that Column will choose C, she should choose C as well. In short, depending on how the agents involved perceive things, a potential PD situation might well turn into a Stag Hunt matrix – or into any other game, for that matter (Skyrms, 2003).

A more radical twist on the interpretation problem can be found in Schick's analysis (2003). Schick has argued that agents might disagree on whether they face a true dilemma even when their options and preferences *are* actually just as described by the PD matrix; the reason is they might not think of themselves as playing a game in the first place. To this effect, Schick distinguishes between *Plights* and *Dilemmas*. Row and Column are in a Prisoner's Plight every time their options and preferences are as exhibited by what has thus far been called a standard PD matrix, and they know them to be so. Suppose by way of concreteness their payoffs are as shown in Figure 3. To be in a true PD, in addition, they should be *in a game*, namely, they should each see the other as now ready to make a choice from among the available options. But this further condition need not be fulfilled. Consider, for example, propositions A and B, where A is 'Column will do as I do' (or better: 'whichever of Cooperate/Defect describes what I do, the same describes what my partner does'), and B is 'Column will do the opposite' (better yet: 'whichever of that pair describes what I do, the other describes what my partner does'). Row might then organize things along the payoff structure shown in Figure 5.

Row does not know what Column will do, so Row does not know whether A or B is true; moreover, she supposes A and B to be probabilistically independent of her own choices (for alternative perspectives that question this assumption, see Section Rationality Considerations). Notice that Column cannot think of A or B as actions that are open to her; hence, this is no longer a game setting, but a one-person decision problem. As there is no longer a dominant option, it may well be rational for Row to cooperate (i.e., to remain silent). Column, in turn, may also organize things in terms of A/B, in

		Column	
		C	D
Row	C	4, 4	0, 3
	D	3, 0	3, 3

Figure 4

		Column	
		A	B
Row	C	3, 3	0, 4
	D	1, 1	4, 0

Figure 5

which case she will also be dealing with a one-person decision problem. The upshot is that people are not always playing games; sometimes they do not think in terms of the other's choosing and acting on their options. Once again, this line of reasoning is not meant to offer a way out of the dilemma. But it does point to the fact that there might be fewer dilemmas in real life than what we could have first assumed.

Rationality Considerations

Thus far we have taken the standard game theoretic analysis of the PD for granted; the generic matrix in **Figure 2** could be interpreted as embodying a *dilemma* because the theory sanctions as rational a Pareto-inferior outcome. In the light of this, it might be contended that our pre-theoretical concept of rationality is not fully determined or that there is more than one such concept at stake. This, in turn, has led some authors to question the legitimacy of the standard analysis and the use of dominance rules to solve the PD matrix.

According to Davis (1977, 1985), for instance, once we assume that the players have common knowledge of rationality as well as of the fact that they face a perfectly symmetrical predicament, we are bound to conclude that they cannot but choose alike; outcomes in which one of them defects and the other cooperates are just not possible. Hence each player can only choose between defecting while the other also defects, and cooperating while the other also cooperates. The only rational thing to do for both players is then to cooperate (for an extensive criticism of this argument, see Binmore, 1994). Interestingly, Davis does not question the standard game theoretic analysis when players are not assumed to have common knowledge of the fact that they are perfectly rational agents.

More generally, it has been suggested that PDs might be a symptom of a deeper conflict between Bayesian intuitions and equilibria concepts from game theory. Consider a PD-like matrix in which the choices of Row are not probabilistically independent of those of Column. Suppose Row judges the probability that Column will choose C conditional on Row's choosing C to be close to one; *ditto* for the probability that Column will choose D conditional on Row's choosing D. In this case, Bayesian rationality seems to indicate that Row should choose C, as C's expected utility is greater than D's. The same argument applies to Column; both Row and Column can judge each other to be expected utility maximizers, and hence, they ought to make choices that fail to yield a Nash equilibrium (Levi, 1997). Thus, as long as each prisoner has reasons to perceive her partner as sufficiently similar to herself (so as to be very likely to make the same choices), we have a PD scenario which, arguably, does not lead to a true dilemma.

These and similar suggestions have been criticized on the grounds that, in a PD matrix, each agent gets to choose independently of what her partner does. Therefore, even if there were a probabilistic dependency between the options, there is no *causal* dependency; therefore, in this case weighting each agent's utilities with conditional probabilities is bound to yield the wrong verdict.

Proposals about what a rational agent should do when probabilistic and causal dependency come apart, however, remain controversial. Discussions on this topic have been fueled by Robert Nozick's description of *the predictor's paradox*, better known as *Newcomb's problem* (Nozick, 1969; see Lewis, 1979, for an argument to the effect that Newcomb's problem is just a PD). Suppose an agent can choose between (1) the content of an opaque box; or (2) the content of both the opaque box and a transparent one, which is seen to contain $1000. Obviously, (2) appears to be a dominant option. As it happens, however, the opaque box contains 1 million dollars if and only if a very reliable predictor of human behavior has already predicted that the agent will go for option (1), and nothing otherwise. Notice that, in the usual reading of the problem, the probability of there being a million dollars in the opaque box conditional on the agent's choosing (1) is very large; the probability of there being a million dollars in the opaque box conditional on the agent's choosing (2) is very low. This is so even though, of course, the agent's choices cannot cause the money to appear in the box; either the money is already there, or it is not. Assuming utilities are linear with money, the expected utility of option (1) is close to one million, and that of option (2) is close to 1000. Thus, as in the PD scenario enriched with probabilities that were described in the earlier paragraphs, in Newcomb's setting there appears to be a conflict between choosing the dominant option (2), and choosing the one with the largest expected utility (1) (see **Figure 6**).

To account for this conflict, in the wake of Newcomb's paradox, some authors have sought to develop a *causal* brand of decision theory. In some of its versions, causal decision theory advises us to calculate expected utility using probabilities of counterfactual conditionals (which are meant to be sensitive to causal links) rather than standard conditional probabilities. Hence, every time there is causal independence between acts and possible states of the world, we will obtain those options with the highest expected utility, thus calculated, to coincide with dominant options (Gibbard and Harper, 1978; Lewis, 1981). The fact remains, however, that agents who choose the dominated option in a Newcomb's setting are on average at a better advantage than those who stick to the dominant one – just as, in a PD, a pair of cooperative agents end up individually better off than a pair of defectors. Once again, we could take this fact as evidence of a clash between different underlying notions of rationality; alternatively, it has also been contended that, if a setting is such that *irrationality* is rewarded, then there is nothing our theory can (or should) do about it. (See the collection of papers in Campbell and Snowden, 1985 for a broader perspective on this discussion, including articles arguing that

	The opaque box contains 1 million dollars	The opaque box does not contain 1 million dollars
(i) One box	1 000 000	0
(ii) Two boxes	1 001 000	1 000

Figure 6

morals drawn from Newcomb's setting should be taken *cum grano salis*; for a sympathetic and thorough presentation of causal decision theory, see Joyce, 1999).

N-Persons PD

Mainstream social sciences have identified many instances of conflict between individual and collective rationality. Mancur Olson argues that the mismatch between individual incentives and collective benefits might hamper collectively beneficial actions (1965). Russell Hardin claims that the same discontinuity between individual interests and collective benefits accounts for the depletion of common resources (Hardin, 1971). This kind of phenomena involves the participation of many individuals. A natural question to consider is whether these situations can be modeled as multipersons PDs.

Russell Hardin was among the first to conceptualize collective action problems as *N*-person PDs (1971, 1982). Dawes did the same with the tragedy of the commons (1980). Collective action problems occur when it becomes necessary to mobilize many agents – eventually all of them – in order to provide a nonexcludable good that is beneficial for the group but that requires costly behavior on the part of the individuals. The tragedy of the commons occurs when players fail to form a self-restrained coalition to avoid the depletion of common resources.

The distinction between situations and matrices that we have introduced in earlier sections is relevant here as well. As we have said, Hardin and Dawes attempted to show that collective action problems and the tragedy of the commons are essentially PD situations that can be translated into a PD matrix. Michael Taylor adds a note of caution. He argues that some cases of collective action can be modeled as assurance games involving many players (Taylor, 1987). The issue is not without theoretical and practical significance. Hardin claims that, given that Olson's collective action problems are essentially *N*-person's PDs, any analysis prescribing a solution for the PD must prescribe a similar solution for the collective action problem (Hardin, 1982). Naturally, this will not be possible if, as Taylor holds, there are competing game matrices for the same collective action situation.

Philip Pettit extends the issue still further (1986). He distinguishes between two types of many-persons PD. *Free-rider problems* are paradigmatic cases of productive cooperation, in which defectors enjoy the benefits of the cooperative behavior of the others. They parasitize the efforts of the cooperative individuals and they share the benefits of the outcome. In *foul-dealing problems*, on the other hand, defectors get a benefit at the *expense* of the other players. Defectors obtain a benefit that is superior to the benefit that everyone would obtain in case of universal cooperation (Pettit, 1986). The provision of public goods is an example of the free-riding problem. The Hobbesian logic of the state of nature is an illustration of the foul-dealing case. Consider for instance the case of mutual disarm. Defectors not only enjoy the advantage of universal peace, but they also end up in a preeminent position – being armed in a disarmed world at the detriment of others.

Iterated PD, Two Persons

Consider now a repeated PD. In games of repeated interaction, the possibility of future contact becomes crucial for deciding whether or not to cooperate. There are two possible scenarios. In one of them, the game is finitely iterated and the players know the number of encounters. In the other case, iteration is infinite or of unknown length. Mainstream game theory treats these two situations differently. There are, however, empirical data that challenge the adequacy of this analysis.

Finitely Iterated PD

The analysis of finitely repeated games is similar to that of one-shot games: rational players should not cooperate. The last move in a finitely repeated PD *is* a one-shot PD having defection as a dominant strategy. Assuming common knowledge of rationality and common knowledge of the length of the game, defection propagates by backward induction to the earlier moves. For the sake of concreteness and without loss of generality, in **Figure 7** we have represented an iterated PD in extended form. The game has two moves for each player, and the red line divides the first instance of the game from the second one. The game is played simultaneously by each one of the players, starting by player 1. Payoffs are represented with ordinal numbers.

Backward induction reasoning mandates thinking from the end of the game to the beginning. Thus, player 1, before choosing whether to cooperate or to defect, calculates what player 2 will do in each possible ending of the game. In the upper branch of the tree, for instance, player 2 will need to choose between cooperating (3,3,3,3) or defecting (3,3,1,4). In case the game arrives to that point, rationality requires for player 2 to defect. Player 1 will continue doing these calculations *for each ending point*, before deciding his own behavior at the starting of the game. By backward reasoning, player 1 is able to deduce player 2 ultimate choices, restricting his own available options. This reasoning delivers universal defection (a result that is represented by the lowest line in the graphic). Note, however, that the equilibrium outcome (2,2,2,2) is evidently Pareto-inferior with respect to universal cooperation (3,3,3,3).

Experimental data provide a less conclusive picture. In theory, rational players must always defect. In practice, however, a well-established empirical literature shows that players tend to behave cooperatively at the beginning of the game and defect when the end of the game is approaching (Selten and Stoecker, 1986; Andreoni and Petrie, 1993). This finding casts doubts on the psychological plausibility of the backward induction method and it blurs the distinction between finitely and indefinitely repeated PDs.

An interesting literature has emerged to scrutinize this issue (Pettit and Sugden, 1989; Binmore, 1997; Kreps et al., 1982). Kreps et al. (1982) argue that small doses of incomplete information can account for the experimental findings showing cooperation in the early stages of the game. Suppose that one of the players believes that there is some chance for the other to behave irrationally; in that case, it is also reasonable for her to behave irrationally and cooperate. The argument applies in reverse mode to the other player,

Figure 7

reinforcing the belief that he has an irrational opponent. Relaxing the assumptions of common knowledge of rationality and allowing for incomplete information generates drastic changes in the way the game is supposed to be played.

Indefinitely Repeated PD

Indefinitely repeated PD involves cases where the players ignore the length of the game. Most models assume a probability measure indicating the chances of future encounters. A discount factor could also be included in order to calculate the present value of future payoffs. The relevance of these assumptions depends, among other elements, on the nature of the encounters – on whether agents are involved in pairwise interactions or simply playing the field.

Game theorists analyzed a wealth of contingent strategies. So-called nice strategies are never the first to defect. An example is GRIM, which starts cooperating, but when the opponent defects, it defects as well, and continues defecting irrespectively of the behavior of the other player. Another example is TIT-FOR-TAT (henceforth, 'TFT'). TFT always starts by cooperating, and then does what the other player did on the previous move.

TFT has a number of interesting features: (1) As stated, it is a nice strategy: it will not defect before its opponent does; (2) it is also retaliating: it will respond to a defection by defecting as well; (3) it is forgiving: if the opponent, after having defected, returns to cooperation, TFT will respond by cooperating again; and (4) TFT is non-envious: it just attempts to do as much as it can, irrespective of what the opponent is doing.

In the early 1980s, Robert Axelrod invited researchers to submit computer programs implementing strategies to be pitted against each other in a PD repeated 200 times. Devised by Anatol Rapoport, TFT entered the scene as one of the 14 programs in the competition (Axelrod, 1984). TFT, which obtained the greatest sum of payoffs over all plays, was declared the winner. Sometime later Axelrod repeated the experiment, allowing for new strategies to enter the tournament; this time he used a probabilistic termination rule to avoid end-game effects. At that point 63 strategies took part of the competition. Researchers were aware of the previous results as well as of the score obtained by TFT. Some new strategies were thus specially devised to counter TFT, such as TIT-FOR-TWO-TATS, sponsored by John Maynard Smith. TFT won again.

These results need to be carefully interpreted. To begin with, notice that TFT is not the best strategy *simpliciter*; it is only the best in the sense that it obtained overall the greatest sum of payoffs. Several strategies were able to defeat TFT on one-to-one competitions. The success of TFT was possible because it added the benefits of cooperation *across* competing strategies. The nature of the tournament was decisive for this success: in a tournament that matched strategies pairwise and only

allowed the winner of each pair to continue the competition, TFT could have been eliminated early (Axelrod, 1984). Second, the fact that the tournament was played by automata was significant because it ruled out mistakes. In a competition where mistakes or trembles are possible, TFT might be provoked by another TFT by mistake, triggering an escalating process of mutual defection. TFT does not have any instruction to stop such escalations (Axelrod, 1984). Last but not least, the results obtained by Axelrod depended largely on the original setting. The starting point of the tournament only included a limited number of strategies; many other possibilities were excluded for no good reason. The advantages of TFT are then dependent on the existence of alternative strategies actually available in the population (Binmore, 1998).

Evolutionary PD

The PD can also be interpreted in evolutionary terms. In this context, large populations adjust their strategies in agreement with the strategies available in the environment. Payoffs express the fitness of specific phenotypes; they reflect the differential spread of strategies in the environment. Note that they are conceived of as true automata: they do not *choose* to cooperate or defect, they are rather wired to behave in certain ways. For the sake of concreteness, imagine a population with two different phenotypes: defectors and tit-for-tatters. We assume the typical replication dynamics that describes the change in the long run of the relative frequency of a set of phenotypes under the condition that they produce error-free copies of themselves. In the replication dynamics framework, behaviors with above-average fitness increase their frequency in the population. The focus is specifically on the role of selection; mutations are not explicitly modeled, but it is assumed that they disturb the system, albeit in an isolated manner. We assume, moreover, that interactions occur on random pairs n times, and that the payoffs for each interaction are cardinally represented as in **Figure 1**.

If two defectors meet each other, they each obtain -10 multiplied by the number of plays; to wit: $-10n$. If two tit-for-tatters meet each other they obtain $-3n$ each. The case in which a defector meets a tit-for-tatter is more interesting: in this scenario the tit-for-tatter obtains -25 and the defector -1. However, the tit-for-tatter will retaliate all along the remaining moves of the game, obtaining in the second move -10 for himself and -10 for the defector. This can be represented as $-10(n-1)$. When playing against a tit-for-tatter, the defector gets $-1+(-10)(n-1)=-10n+9$, and the tit-for-tatter gets $-25+(-10)(n-1)=-10n-15$.

We introduce now the information concerning the proportion of each phenotype in the population. Let us represent the proportion of tit-for-tatters in the population by x. The expected payoff for a defector is

$$x(-10n+9)+(-10n)(1-x). \qquad [1]$$

Whereas the expected payoff for the tit-for-tatter is

$$x(-3)n+(1-x)(-10n-15). \qquad [2]$$

We now combine [1] and [2] into the following inequality:

$$[x(-3)n+(1-x)(-10n-15)>x(-10n+9) + (-10n)(1-x)]. \qquad [3]$$

Solving for x, we obtain all the values at which tit-for-tat is fitter than defection:

$$x>15/(7n+6). \qquad [4]$$

Notice the importance of the value of n in [4]: the greater the value of n, the lower the value of x. This means that the longer the play of game, the easier for tit-for-tatters to spread, because x and n are inversely related. At the exact point in which the right side and the left side of [3] equate, there is a balancing point; at that point the population is polymorphic with exact proportions of tit-for-tatters and defectors coexisting side by side. This co-existence, however, is not stable: any mutant that modifies the proportion in the strategies available in the environment tips the balance and pushes the population toward one extreme or the other (all tit-for-tatters or all defectors). If the new entrant is a tit-for-tatter, the population evolves toward a situation where every phenotype is a tit-for-tatter. If the new entrant is a defector, the whole population ends up being composed of defectors. These two extreme situations (all phenotypes are tit-for-tatters or all are defectors) represent two possible monomorphic equilibria. These equilibria are stable; they are robust enough to resist the entrance of new exemplars of the opposite phenotype.

This analysis is simplified in different ways. To begin with, note that we are comparing only two strategies: defection and TFT. If more strategies are allowed into the picture, the analysis becomes more complex (Nowak, 2006). Second, as we have already said, we modeled the game using the traditional replication dynamics in an infinite population setting where strategies are randomly paired. This model might not take into account important features. Paring strategies randomly do not capture geographical effects that might be of paramount importance for cooperation (Axelrod, 1984).

Geographical effects can emerge in different ways. One possible line of analysis consists in making local interaction derive from exogenous factors. Imagine a population where some members tend to interact with individuals that are like themselves according to some arbitrary phenotypic trait. If this trait is correlated to cooperativeness, we should expect clusters of cooperators that meet each other using that specific trait as clue. Neighboring effects can be also endogenously generated. Although the original interaction is random, subsequent interactions can be modeled as a Bayesian process in which individuals *adjust* the frequency of their interactions according to prior successful interactions with specific individuals (Skyrms, 2004). Other models use cellular automata that exclude memory, relying exclusively on the state of the neighbors' neighbors (Nowak and May, 1992). These models have the potential to account for the formation of clusters of cooperativeness in a way that the process of random pairing might neglect.

Abstract

Outside of execution, incarceration is the most severe form of punishment used by modern societies. This article describes the origins of prisons and imprisonment, offers comparative statistics on incarceration rates, discusses theories of punishment, highlights unanticipated consequences of incarceration, and suggests potential ways to make punishment more effective.

Origins: How Did Prisons Develop?

Prisons are used to house individuals convicted for serious crimes. However, few people are aware of how prisons developed. In fact, early nineteenth century American prisons were not thought of as punishment. The idea of incarcerating someone as punishment was unheard of. Prisons were developed as a liberal reform to stem abusive punishments. Locking people in prisons was believed to be costly and overly sympathetic. Why did the prison become the central form of punishment? What changed to bring about incarceration? What goals were prisons to achieve? How does punishment reflect broader social features? This article addresses these questions.

Prisons are not a natural feature of society. Rather, for much of Western development societies relied on banishment, physical punishment, and executions. Some common punishments included cutting off portions of an ear or finger, whipping, branding, and the wheel. These punishments were carried out in front of large crowds, and sent a message to onlookers of what happens to criminals. Additionally, these punishments left visible marks to stigmatize individuals. This way, if an individual showed-up in a town missing part of his/her ear or finger, others would know that he/she was a criminal.

Prisons are a construction of nineteenth century social, political, and economic developments. Rusche and Kirchheimer (1968) demonstrated that physical punishments slowly gave way to incarceration as new economic forms emerged. During the nineteenth century, urban industrial capitalism replaced agrarian production and mercantile exchanges. Industrial production required large populations of able-bodied workers to operate factories. Urbanization required people to leave their small rural communities and migrate to central cities. Prior to this time, perceptions of crime and criminals were much different. In Rothman's (1971) historic treatise, *The Discovery of the Asylum: Social Order and Disorder in the New Republic*, he explained the shift from accepting crime, poverty, and insanity as natural elements of the community to the emergence of scientific understandings and interpretations of these issues as social problems. Colonial Americans saw crime and other forms of deviance (e.g., poverty, insanity) as natural parts of social organization that needed to be controlled, deterred, and contained, but never thought they would be eliminated (Rothman, 1971). Urban congestion, separation from family members, and lack of strong social ties to community, required larger governmental responses to crime, insanity, and poverty. No longer could people rely on informal social networks. This created a need for new kinds of formal social control and assistance, in which the asylum, prisons, and welfare supports emerged simultaneously. Urban industrialization did not cause these responses to social problems, per se, but this reconfiguration of community necessitated new forms of control and assistance.

The prison was developed with the ultimate goal of fixing or rehabilitating inmates. Michele Foucault (1977) characterized this shift in goals for punishment as a move from 'punishing the body' to 'punishing the soul.' The initial forays into incarceration date back to the sixteenth century with jails, poorhouses, and workhouses, but these were sparse and typically locally operated facilities in which individuals were housed in horrid conditions. Foucault (1977) depicted a movement spanning from around the 1770s to the 1860s in which prison developers became focused on changing inmates' behavior. By punishing the soul, Foucault referred to the religious instruction, vocational training, and inclusion of psychiatric sciences in prisons to adjust the way inmates thought and acted. This orientation explains why prisons were referred to as houses of correction, and, currently, US prisons are part of state-based Departments of Corrections. Behavioral change became a central stated goal for prison administrators, policy makers, and reformers. But, many continue to question how well prisons have achieved this goal.

The United States was an early adopter of imprisonment with prisons built throughout the nineteenth century. In New York, the Auburn prison, opened in 1819, and, in Pennsylvania, prisons opened in 1826 and 1829, in Pittsburgh and Philadelphia, respectively (Rothman, 1971). The Auburn system was known as the congregate system in which inmates slept in individual cells, but worked together during the day in silence. The Pennsylvanian prisons were more concerned with separation and introspection, including inmates never seeing other inmates. Inmates worked in solitude in their cells and only spoke with guards and chaplains. Silence, separation, and introspection were seen as tools to teach prosocial values and compensate for the poor upbringings and lack of discipline that were believed to cause criminal behavior. Prisons were to instill in inmates the needed discipline that their childhoods' lacked. Rothman (1971: p. 97) quotes Tocqueville and Beaumont after their visit to US prisons, in 1831: "Everything passes in the most

profound silence, and nothing is heard in the whole prison but the steps of those who march, or sounds proceeding from the workshops … We felt as if we traversed catacombs; there were a thousand living beings, and yet it was a desert solitude."

These US penal models quickly spread to other states and countries. The prison was seen as replacing the horrible conditions of the jails and other crude forms of confinement. Reformers concentrated on psychiatric approaches to train inmates to return to society as prosocial individuals. The prison has vacillated between emphasizing punishment and retribution vs rehabilitation and reentry since its inception. Currently, penal administrators and policy makers grapple with ways to balance these contradictory goals.

Comparative Incarceration Rates

Social scientists use comparisons to explain similarities and differences across units of analysis. The most prevalent measure of the size of incarcerated populations is reported as a rate per 100 000 people in the country. This measure gives the relative number of people in prisons and allows for making some comparisons across countries and within countries over time. When analyzing incarceration rates, it is obvious that there is tremendous variation in incarceration rates. Comparative research is hampered by making sure that the countries being compared are similar in several important ways. For instance, it is difficult to make comparisons between the United States and small nonindustrial countries or between countries with totalitarian regimes. Instead, researchers compare the United States to other advanced capitalist democracies.

The United States incarcerates between seven and ten times the proportion of adults as other Western democratic countries. There are currently more than 2 million adults incarcerated in the United States, which results in an incarceration rate of 719 per 100 000 (World Prison Brief, 2013). This incarceration rate reflects a break with previous times. From 1925 to 1975, the US incarceration rate fluctuated between 90 and 180 per 100 000. Then, in the mid-1970s, there were a series of changes to the criminal justice system that fostered a steady increase in incarcerated populations. Some of these changes include replacing indeterminate sentencing with determinate sentencing, the drug war, three-strike laws, zero tolerance ordnances, more police, and more aggressive prosecution of cases. These changes reflect a new orientation toward imprisonment that emphasized punishment and retribution. Although there are several explanations for this change, many scholars point to the publication of a research article in which it was argued 'nothing works' in correctional rehabilitation (Martinson, 1974). The nothing works report provided academic support for the notion that prisons do not actually 'correct' people. And, if rehabilitation is impossible, then, agencies should no longer focus on behavior change.

How do the US incarceration rate trends fit with other countries? Typically, comparative researchers compare advanced capitalist countries found in the West. This research groups countries according to politics and culture such that Anglo-American, Continental European, and Scandinavian countries fit together on a series of policy outcomes (e.g., economics, incarceration, welfare spending) (Cavadino and Dignan, 2006; Esping-Anderson, 1990). For instance, in Scandinavia, throughout the post–WWII period, incarceration rates fluctuate between 45 and 70 per 100 000. One exception of this is Finland's incarceration rate, which, throughout the 1960s, averaged 145 per 100 000. However, this rate reflected Finland's cultural attachment to Russia and included many political prisoners. As Finland became more incorporated in Scandinavian culture, politics, and law, policy makers embarked on a decarceration movement that included inmate amnesties and early releases. Finland now incarcerates about 60 per 100 000 population (World Prison Brief, 2013).

Continental European incarceration rates are slightly higher, on average, than Scandinavian countries. These rates fluctuate between 65 and 110 per 100 000 throughout the second half of the twentieth century. This is not to suggest complete homogeneity among these countries. Austria, for instance, had an average incarceration rate, in the 1960s, of 113 per 100 000 and in the early 2000s, the average rate was 88 per 100 000. Belgium, France, Italy, and the Netherlands, however, all experienced incarceration growth. The Netherlands provides an interesting case because the average incarceration rate was 25 per 100 000 through the 1960s, but, in the early 2000s, the rate jumped to 89 per 100 000. David Downes (2001) explained this incarceration rate growth as a product of social and criminal justice changes, namely, prosecutors became more aggressive and prison waiting lists were eliminated. Downes' research highlights the fluid nature of imprisonment as a product of policy decisions.

Although the United States is the most aggressive punisher among the West, the Anglo-American countries stand out compared to other Western countries. These countries have average incarceration rates that fluctuate between 73 and 700 per 100 000 from 1960 to 2002. Australia, Canada, Ireland, New Zealand, and the United Kingdom all had increasing incarceration rates throughout this time frame. Australia, New Zealand, and the UK incarceration rates more than doubled from averages ranging between 65 and 73 per 100 000 to 129 and 152 per 100 000. These advanced capitalist countries display different ranges of acceptable levels of punishment in which Anglo-American countries have the greatest tolerance for punishment and Scandinavian countries have the lowest thresholds.

Explanations of Comparative Incarceration Rate Differences

Several criminologists have tried to explain cross-national incarceration rate differences and temporal changes. These explanations typically build on two classic theoretical perspectives: (1) Emile Durkheim's cultural thesis and (2) Marxian conflict perspectives. Durkheim suggested that punishment reflects cultural norms, and the act of punishment furthers cohesion around such norms. He argued that crime and punishment are functional societal features. Marxian perspectives differ by emphasizing the role of punishment to maintain class boundaries and, essentially, punish the working classes as a central weapon in class conflict. The most compelling contemporary explanations of incarceration rates integrate the functional and conflict perspectives by

recognizing that punishment solidifies cultural norms and it also disproportionately impacts the most disadvantaged in society.

The leading comparative explanations of incarceration rate variation capture structural and policy differences. Garland (2001) suggested that the United States and the United Kingdom have cultural preconditions making them more susceptible to harsh criminal justice responses to crime and deviance. Cavadino and Dignan (2006) and Downes and Hanson (2006) found that incarceration rates are inversely related to welfare provisions such that some countries emphasize inclusive, as opposed to exclusive, approaches to addressing crime, deviance, and poverty. There is a growing body of research that emphasizes political–economic differences such that the influence of conservative political institutions – referred to as neo-liberalism – increase incarceration rates, compared to more egalitarian politics – referred to as corporatism that are less reliant on incarceration (for review, see Jacobs and Jackson, 2010). Greenberg (1999), Jacobs and Kleban (2003), and Sutton (2000, 2004) have all found similar results in which the left-oriented corporatist policies found in Scandinavia and Continental Europe support lower incarceration rates, compared to more conservative politics found in Anglo-American countries.

Other criminologists have extended these political–economic perspectives to suggest that there are specific legal differences contributing to incarceration rates. Savelsberg (1994) and Whitman (2003) found the influence of organizational differences between European and Anglo-American criminal justice agencies consequential for punishment outcomes. Namely, in the former, practitioners are considered trained civil servants and have the ability to make decisions without concerns of public disappointment. Conversely, Anglo-American criminal justice practitioners work in legal environments – i.e., common law – in which public participation and social interests are more easily reflected. Features such as case-based law development, independent juries, and broad prosecutorial discretion are suggested to make it easier to respond to public desires for harsher punishments. Lacey (2008) extended this argument when she pointed out that political dynamics are important, and argued that researchers need to consider differences in how practitioners are selected, trained, and operate throughout their career. Advancing her perspectives, DeMichele and Janoski (2010) showed that differences in lay participation, judicial power, and different rules of evidence are consequential for incarceration rates. The consensus among these explanations is that politics and legal differences are essential to understanding comparative incarceration rate variations.

Unanticipated Consequences of Incarceration

Social policies have the potential for unanticipated negative consequences. The notion of unanticipated negative consequences was identified by Robert Merton (1936: p. 894) as an important area for sociological study. Unanticipated consequences are often related to policy makers lacking knowledge of causal mechanisms, simply making mistakes, following a priori beliefs, and incorrect predictions about outcomes (Merton, 1936; Payne and DeMichele, 2011). Several criminologists have called attention to unanticipated negative consequences stemming from US mass incarceration. Simply, despite the planning and preparation put into correctional policies, mass incarceration has resulted in several deleterious outcomes for inmates, neighborhoods, and society.

Correctional officials and policy makers too often develop policies in the aftermath of highly publicized outrageous crimes. Roger Roots (2004) demonstrated how governmental responses to some social problems are developed in such a hurry, and, as such these policy makers have little chance of thinking through potential unanticipated consequences. Roots identified times when well-intentioned laws may have actually 'backfired' to exacerbate the plight of the poor, single women, elderly, and others for which social policies were directed to help. Criminologists have identified several unanticipated consequences related to mass incarceration. Most of these consequences make it more difficult for the formerly incarcerated to return to society.

Much as premodern forms of punishment sought to 'mark' offenders with physical signs of their criminality, contemporary practices stigmatize offenders in many ways that prevent them from fully participating in society. For instance, felony voting restrictions prevent millions of Americans from voting. Sex offender registration and housing requirements prevent individuals from living in many communities and increase the likelihood of such individuals hiding from treatment parole agents (i.e., absconding). Similarly, having a drug conviction prevents people from acquiring financial aid to attend college. In many states, any felony conviction can permanently block individuals from receiving welfare support, and now many forms of employment require disclosure of convictions and compliance with a background check.

The problem with these sorts of collateral consequences is that they exacerbate the criminogenic effects of incarceration. That is, such policies do not reduce criminal propensities, but rather they create a context in which offenders have blocked opportunities to engage in prosocial lifestyles. The final section of this article introduces readers to ways in which crime control policy makers can incorporate more effective strategies to alleviate the potential for unanticipated negative consequences of incarceration.

Potential Improvements

Correctional policy makers have the opportunity to institute approaches that improve the chances for offenders to succeed in the community. Although Martinson (1974) argued that nothing works in correctional rehabilitation, other researchers have identified principles of effective corrections. MacKenzie (2006) provides one of the more thorough reviews of effective correctional strategies. She focuses on strategies because this is a broader concept including different programs, policies, and interventions. The emphasis of her book is to call attention to how correctional strategies can focus on achieving crime and recidivism reductions, not just punishing offenders. The agenda is to use scientific research

to understand the effect of correctional strategies to foster crime reductions. What sort of things should correctional administrators and policy makers concentrate on to reduce crime? MacKenzie (2006: p. 59) identifies several criminogenic needs – i.e., malleable individual traits related to crime – to be addressed: procriminal attitudes, procriminal associates, impulsivity, weak socialization, risk taking, and deficits in educational, vocational, and employment skills. Research finds that focusing attention on these types of offender characteristics can bring about the greatest impact on crime reductions.

Adopting effective correctional strategies requires administrators, policy makers, and the public to move away from traditional concerns for punishment alone. The mass incarceration movement has fostered overcrowded prisons, removed treatment and training from prisons, and created an environment rife with violence and gang membership. MacKenzie (2006) makes clear that punishment alone is not enough. Instead, research finds that strategies that rely on swift and certain responses to criminality are more effective than simply inflicting pain on offenders. It is ironic that prisons developed as a way to improve the horrible conditions of jails and workhouses, and to end the brutality of physical punishments. But, at least since the mid-1970s, US prisons have shifted away from concerns with *correcting people* to adopt strategies that focus on managing populations of the most disadvantaged in society and warehousing them in environments that make personal improvements nearly impossible. Does anyone suspect that sending people to these overcrowded, violent, and no-frills prisons will result in good citizens? Research makes clear that locking people up and throwing away the key is an ineffective strategy that diverts from the original intentions of imprisonment.

This article is a revision of the previous edition article by R. Boruch, volume 18, pp. 12070–12072, © 2001, Elsevier Ltd.

Abstract

This article covers basic definitions and frameworks for assuring the confidentiality of individuals' records that are generated or acquired in social research. The latter includes observational studies, surveys, and randomized experiments. Good professional practice, ethics codes, and law are all considered. To the extent possible, experience and practice in different countries is also handled.

Introduction

This article begins with basic definitions of privacy, confidentiality, and security. It covers the legal and ethical obligations that researchers have in some countries to establish and maintain responsible 'data stewardship' practices that include assuring individual privacy and the confidentiality of research records. Different ways to minimize degradation of privacy, recognize individuals' rights, and enhance confidentiality of records with identifiable information are described. This article then outlines strategies for making records accessible for statistical analysis while preserving privacy protections. Examples are drawn heavily from experience in the United States, but we recognize related important work in other countries.

We define social research here as efforts to develop generalizable scientific knowledge about a phenomenon or group. We distinguish this activity from research dedicated to making judgments about particular individuals or groups as in the case of administrative decisions in the courts or social support systems, for example.

Definitions

For contemporary and earlier analysts, the terms privacy, confidentiality, and security reflect an amalgam of personal and socio-cultural values. As Acquisti (2004) observes, the fundamental concept of privacy will mean "different things to different people, including the scholars who study it, and raises different concerns at different levels" (p. 150). Privacy in this article broadly refers to a person's right to control the information about himself or herself (e.g., Boruch and Cecil, 1979; Duncan et al., 2011). The idea of privacy engenders respect for an individual's autonomy in sharing personal attitudes or experiences with others and his or her freedom from excessive intrusion.

While privacy concerns individuals' autonomy, confidentiality refers to the status given to information that individuals provide to the researcher. This status involves regulating or prohibiting the disclosure of personal data on an identifiable individual. A recipient of such personal data is usually bound by legal agreement, obligation, or promise to not release information about data providers without the individual's consent unless certain exceptional conditions are met.

Security here pertains to safeguarding physical or electronic records so as to provide protection against unauthorized access and misuse. Security measures might include physical controls (e.g., locks or guards), personnel policies (e.g., background checks), data-system controls (e.g., passwords or encryption), or other special procedures (Goldman and Mulligan, 1996).

An Ethical and Legal Context

Participants in social surveys, randomized field trials, or other research in the behavioral and social sciences entrust personal information to researchers. In contemporary social research, administrative records on identifiable individuals may also be disclosed to researchers in the interest of assisting an organization in improving its functioning and achieving its mission. Generally, researchers or recipients of such data have ethical and legal responsibilities associated with their becoming stewards of these data. The concept of 'data stewardship' refers to a researcher's managing of personal data in an effort to assure individuals' privacy, confidentiality of information, record security, and beneficent use of the data for advancing societal understanding of a phenomenon.

Concerns for responsible data stewardship are reflected in international and professional codes of ethics. For instance, Principle 6 of the United Nation's Fundamental Principles of Official Statistics formalizes the idea that all individual data collected by statistical agencies or organizations must be kept confidential and used exclusively for statistical purposes. The European Commission's Community Research and Development Information Service offers comparable guidance on privacy and confidentiality. In the United States, the Census Bureau distinguishes data stewardship as a formal process that 'goes beyond the law' to ensure respect for privacy and release of high-quality information about the nation's population (U.S. Census Bureau, 2012). Commitments to ethical data stewardship are also reflected and reified in U.S. federal government regulations such as the Federal Policy for the Protection of Human Subjects, known as the 'Common Rule,' and institutionalized review processes such as Institutional Review Boards. In Canada, among other countries,

comparable review institutions are called Research Ethics Boards.

Laws may also govern data stewardship practices and techniques. For example, the U.S. Privacy Act of 1974 establishes procedures for the collection, use, and dissemination of personally identifiable information provided to federal agencies. Since 2002, the Confidential Information Protection and Statistical Efficiency Act extended federal agencies' disclosure protections to all data obtained under a pledge of confidentiality. Similar statutes dictate confidentiality and data access policies for specific agencies like the Census Bureau (e.g., Section 9, title 13 of the U.S. Code) and the National Center for Health Statistics (e.g., Public Health Service Act). The National Center for Education Statistics and education research initiatives must adhere to at least four federal laws guiding student and family information usage (Duncan et al., 2011). Most such laws (or associated legal regulations) stipulate that disclosure of personally identifiable records without an individual's consent is prohibited except under clearly specified conditions such as imminent danger to the individual or to others.

A number of other developed countries have codified government-wide privacy and confidential guarantees. Sweden's Secrecy Act of 2009 and Data Act of 1973 include penalties for failure to meet data stewardship obligations. Wallgren and Wallgren (2007) provide additional references to contemporary pertinent regulations issued by government statistical agencies in Canada, Denmark, the Netherlands, and Finland. Boruch and Cecil (1979) discuss some early history of these reforms.

Assuring Privacy and Confidentiality in Surveys, Randomized Field Trials, and Other Data Collection Efforts

Ethical codes in the social sciences date at least from 1948 with the Code of Marketing and Social Research Practice issued by the European Society for Opinion and Market Research. Analogous codes continue to be produced and periodically revised by statistical, educational, psychological, anthropological, and other social science societies in many developed countries. Such codes have also been adopted or tailored by some for profit and not-for-profit research entities that do international work, e.g., American Institutes for Research.

To satisfy ethical codes as well as legal demands for responsible data stewardship, a researcher must consider privacy and confidentiality issues at each stage in the process of a study. When first designing a study, for instance, the researcher must seek to minimize the information that is asked of a study participant and tailor questions to both meet a study's objectives and minimize intrusiveness. A researcher may also limit the number of people who are engaged in a study so as to achieve a minimum necessary sample size, a professional standard that coincidentally meets an ethical concern about reducing the extent to which people are asked to disclose personal information.

Under many codes of ethics and certain legal regulations, individuals being recruited for or becoming involved with a study must be told whether their participation in the research is voluntary. People usually must be informed of the purpose of the research and the disposition or functions of the data that they provide. Typically, they must be assured that the information they provide will remain confidential, that is, their responses will be used only for research purposes and personally identifiable information will not be disclosed to anyone else.

During and after a study's completion, a researcher is usually obligated to cooperate with courts and other government agencies if such organizations demand information on identifiable individuals who happen to be involved in research. In certain circumstances, however, one can assure data providers of the confidentiality of the information they provide despite government threat or legal action. For instance, the National Institutes of Health requires grantees in the United States who research delinquent activity, illicit substance use, or certain other sensitive behaviors to issue documents called Certificates of Confidentiality. These certificates protect investigators legally against 'involuntary disclosures' of names or identifiable information of their research subjects by judicial or administrative subpoena. That is, the researcher who collects sensitive information cannot be forced to disclose identifiers. The role of such Certificates is discussed in the context of research on children, for example, in reports issued by the Institute of Medicine in the United States (Field and Behrman, 2004) and by Boruch et al. (2012) more generally. We are aware of no similar statutory protection in countries other than the United States, and the Certificates apply only to records maintained in the United States.

Certificates of Confidentiality, however, cannot be treated as ironclad guarantees. In the wake of the 11 September 2001 attacks, the U.S. government created new powers to access personal information. The U.S. PATRIOT Act, for instance, permits the U.S. Attorney General to petition courts for *ex-parte* orders for the release of Department of Education data that could inform investigation or prosecution of domestic or international terrorism, i.e., who is a student in what course of studies. In light of major policy-making events, keeping track of current 'shield laws' protecting investigators and research subjects as well as documenting episodes when assured confidentiality could not be legally guaranteed is important. Boruch et al. (2012) give recent information on vulnerability in the context of the U.S. judiciary.

Similarly, Certificates of Confidentiality do not protect against voluntary disclosures by researchers. When presented with evidence of child abuse, reportable communicable disease, or a subject's threatened violence against one's self or others in a study, researchers may especially wish to convey such information to law enforcement, health and human service departments, or other governmental agencies (e.g., Takas et al., 1995). According to the U.S. Office for Human Research Protection's (2003) guidelines, researchers should indicate in their subjects' consent forms that the researcher may indeed choose to or be required by law to disclose information concerning these subjects. This practice has been widely embraced by the Center for Disease Control and Prevention, National Institute on Drug Abuse, National Institute on Alcohol Abuse and Alcoholism, and other institutions devoted to examining sensitive topics.

Inventive statisticians, economists, and others have also developed useful ways that are useful at times to elicit information from individuals in personal interviews and that do not degrade privacy. As a consequence, they also protect the confidentiality of the information that is provided. One such approach falls under the technical rubric of 'randomized response.'

Randomized response and related approaches involve collecting information that discloses nothing to the researchers about the state of the particular subject or the subject's behavior like use of addictive substances or violations of law. Nevertheless, these strategies, augmented with some elementary statistical arithmetic, produce credible estimates of the incidence of a sensitive trait or behavior in the study. In the simplest cases, each respondent in a sample is asked to randomly choose one of two questions to answer, one of which is innocuous and the other being sensitive. This may be probabilistically based like rolling a die. Which question is answered is not disclosed to the interviewer, nor is the result of the die roll. Rather, the respondent merely gives a 'Yes' or 'No' response. Given simple probability theory and aggregate (not individual) information on incidence for the innocuous question, it is an easy matter to compute the proportion of respondents who have the sensitive characteristic. But there is no way to determine individual status with certainty.

The basic approach and arithmetic of randomized response is given in epidemiology texts such as Levy and Lemeshow (2008). In the Netherlands, Lensvelt-Mulders et al., 2005 summarize recent evidence on its value. Statisticians from Cuba and Spain have also handled the topic (e.g., Bouza et al., 2010). Boruch and Cecil (1979) further review early empirical evidence on the approach's value.

Data Sharing, Privacy, Confidentiality, and Researchers' Use of Statistical Databases

Making local, regional, or national data available to other researchers presents additional challenges to ensuring privacy and confidentiality. Researchers may make their statistical data available so as to permit secondary analysis, confirmation or disconfirmation of the original findings, and for other scientific purposes. Codes of ethics enunciated by the American Educational Research Association (AERA), and the American Psychological Association (APA), among others, have even encouraged the practice of such sharing in the interest of advancing scientific understanding. Yet, sharing data may put two ethical standards in tension with each other. It may be publicly beneficial to release data for statistical analysis. But availability of such data may compromise confidentiality and introduce new possibilities for unauthorized, non-research use of personal records. Section 12 of the AERA (2011) Code and the APA's (2012) Task Force Report recognize the tension and provide advice on its handling.

Developing and using statistical databases benefit society at times. To the extent that the same dataset can be put to work frequently to benefit the public, the cost/effectiveness ratio decreases. For instance, in educational research, scholars have undertaken numerous reanalyses of Tennessee's Project STAR class size experiment data. These studies subsequently informed policy debates about reducing the size of classroom in 20 American states. No confidentiality of records issues emerged over the 20-year course of this activity.

While potentially enriching and cost-effective, new statistical databases are blurring the boundaries between publicly useful and traditionally private information. An increasing number of databases are unrelated to social scientific inquiry and help private companies and corporations gather information about consumers. They may nonetheless be used also by researchers. Duncan et al. (2011) discuss a case in point: Iceland.

In the late 1990s, Iceland's parliament passed legislation permitting a bio-pharmaceutical company to construct a centralized health database of all Icelandic people's genealogical, genetic, and health information. The database linked nearly 80% of Icelanders to a national genealogy going back over 1000 years (Hlodan, 2000).

Throughout the early 2000s, genetic biobank projects proliferated in countries as diverse as Taiwan, Estonia, Tonga, and the United Kingdom. The U.S. National Institute of Health also floated a proposal for a large U.S. genomic databank, but budgetary pressures and strong political opposition have halted rigorous debate on this issue (Greely, 2007). These events underscore the fact that as new types of biological, geospatial, audio and video, and social networking data emerge, politicians and researchers must continually reevaluate the boundaries of public and private information, the characteristics of legitimate social science research, and standing policies that protect the individual's rights to privacy.

Learning how to make individual records available for statistical analysis in ways that do not jeopardize the privacy of the individuals who are the source of the record information is not easy. Since the 1970s, federal statistical agencies in the Nordic countries, North America, and many others have sought to reconcile the competing demands of privacy and of data access. Although most government agencies concern themselves with surveys rather than randomized trials on the effects of social programs, lessons learned from agencies' survey experiences help to inform the sharing data strategies for randomized experiments.

The approaches that have been developed to assure researchers' access to existing datasets without compromising privacy concerns can be classified into two categories. The first involves simple, non-legal procedures that focus on assuring that records cannot be used for learning about an individual. The second involves legal arrangements, including statutes, regulations, and contractual agreements discussed briefly below, Boruch et al. (2012) give more detail.

Consider first statistical approaches to making data available and simultaneously protecting individual privacy. Typically, the data steward who releases a record file for the public's use must delete the direct and clear identifiers of individuals from data files. That is, addresses and other unique information are expunged. The custodian may also choose to release anonymized data on a sample of records, rather than on a complete assembly, so as to enhance confidentiality.

Further, because individual records are often detailed and external collateral information is available, sophisticated statistical approaches may be used to eliminate the possibility of deductive disclosure. Such techniques include deleting of

certain variables from the file, eliminating certain micro-records that allow disclosure on small samples of particular individuals, reducing the precision of entry by making the reporting categories crude, introducing controlled random perturbation to true values, and systematically swapping data entries to sever relationships between records and data providers. These technical approaches are often designated as forms of statistical disclosure (deductive disclosure) limitation technology. Advances in this technology have been made by statisticians in the Netherlands, the United Kingdom, Canada, Israel, and Luxemburg and other countries. References and guidance are given in Duncan et al. (2011), Fienberg and Willenborg (1999); Wallgren and Wallgren (2007).

Other individual protections involve legal arrangements at the institutional level. 'Data enclaves' are organizations created to (1) permit intensive sophisticated analyses by people other than the original data custodian and (2) protect the confidentiality of micro-records with the same rules that govern the original custodian. At some academic and research institutions, for instance, enclaves have been established that permit researchers to analyze data that would be accessible ordinarily only to federal civil servants. The rules that govern the data's use, including security procedures and the threat of criminal and civil sanctions, apply to the researchers as they do to the civil servants who are the formal custodians.

A variant on the enclave idea involves licensing agreements. A specific example of this arrangement, developed by the National Center for Education Statistics in the United States, is a license granted to particular individuals to analyze specific datasets that would not otherwise be accessible on privacy grounds. The justifications for such privilege must be made. The licensing agreement includes requirements for security of the micro-records, sanctions, and other rules for disclosure.

Privacy, Confidentiality, and the Use of State Databases in the United States

In the United States, researchers might desire to access the administrative record systems and databases of state governments. Each of the nation's 50 states has its own laws and regulations governing third party access to such data. In particular, state laws may differ appreciably in their provisions for permitting a researcher (and certain others) to acquire and use individually identifiable micro-records. Within each state, data access policies can also differ across systems like schools, hospitals, child welfare and adult welfare agencies, crime and justice agencies, runaway shelters, or other social service institutions.

Currently, no national or state-based compendiums exist for identifying which administrative data systems are legally open or closed to researchers and specifying the conditions of receiving access. The development of these compendiums for various policy spheres serves as one crucial step in helping researchers understand how to properly request and use sensitive governmental data in their studies. In recent decades, some compendiums chronicling the availability of administrative data have been constructed for special purposes. These compendiums describe the structure of particular states' record systems and summarize access rules for nongovernmental actors. For instance, the Office of Juvenile Justice and Delinquency Prevention Research (1995) details state guidelines for procuring administrative records during searches for missing or abducted children.

The Bureau of Justice Statistics (BJS) has been comprehensive in documenting procedures for obtaining criminal history information. The agency has produced 12 reports since 1972; more recent reports supplant earlier ones. BJS' (2002) compendium gives an overview of each state's laws and regulations regarding (1) requirements for state agencies to maintain criminal processing records and (2) policies for disseminating and using criminal history information for noncriminal justice purposes (p. 2). The full text of these laws and regulations can be found in an electronic repository managed by SEARCH, the National Consortium for Justice Information and Statistics. The compendium further outlines the policies of each state on 29 dimensions.

One such dimension is whether the state has enacted laws or regulations concerning the availability of criminal history records to legitimate researchers. About 36 states have provisions governing research access. The BJS cites this compendium assists administrators and policymakers develop fair and effective information management practices. In its own words, BJS proclaims, "The compendia are intended to promote the evolution of enlightened privacy and information policy," (2003: p. 1). For this reason, replication efforts by other agencies or jurisdictions that detail available governmental data and their regulations are critical and valuable.

Privacy, Record Linkage, and Integrated Data Systems

Record linkage, or combining two or more sets of records referring to the same person from different databases in the interest of research, poses another set of privacy problems. Records are often matched according to individual identifiers like names, addresses, Social Security Numbers, dates of birth, or other sensitive information. Interest in record linkage projects has grown as computer technology has made record-keeping easier and policymakers have increasingly relied on rigorous statistical analyses to evaluate the effects of social programs. Organizations like the MacArthur Foundation have begun supporting several initiatives involving integration of administrative records in education, health, and juvenile justice. Similarly, Actionable Intelligence for Social Policy of the University of Pennsylvania has begun to distinguish areas of best practice with respect to integrated data in its commissioned papers.

According to the U.S. General Accounting Office (U.S. GAO, 2001), several types of privacy issues arise from record linkage projects. First, data custodians must deliberate whether consent to linkage is required from their data subjects. Consent may be required in some circumstances, as record linkage typically falls under the purview of data disclosure laws like US Privacy Act of 1974. If consent to linkage is not necessary or cannot be obtained, data custodians might notify data providers of linkage activity. Agreement on consent, disclosure, and notification procedures, however, may be complicated by differences in data policies between agencies or organizations and nations. This may be especially true for countries with governments that are decentralized.

Most importantly, a linked dataset itself may contain more sensitive or detailed information. The concentration of such

information can present greater security risks. Even after removing clear identifiers, a linked dataset may possess enough sufficient information to make re-identification (also called deductive disclosure) possible. For these reasons, public opinion tends not to favor record linkage. Loss of public support can be detrimental to research initiatives. In 2000, the exposure of a relatively unknown governmental database linking the records of 33.7 million in Canada inspired a public outcry that ultimately led to the demise of the county's largest record linkage project (also see Privacy Commissioner of Canada, 2000).

Nevertheless, the case for linkage has to be made in that researchers must weigh potential benefits of record linkage to society against potential costs. An early example of an effort to discover the benefits and costs of linkage for administrative purposes is given in the U.S. GAO (1986a,b). This study determined that certain administrative linkages are not worth the effort. Recent examples, more to the point for social scientists, are offered in the U.S. GAO (2001).

The Future of Privacy and Confidentiality

Independent of governmental interests in assuring confidentiality of personally identifiable research records and social researchers' interests in that aim, private organizations continue to develop massive integrated data systems. The evolution of Facebook, LinkedIn, and similar internet-based activity presents remarkable challenges. For the researcher, understanding how to assure that people are informed about what he or she plans to do with the public data available on such sites, in the face of people's naïve beliefs that the information they post is private, is a complicated matter. Similarly, researchers who wish to understand how to improve online academic courses by accessing test scores have related challenges if they wish to link test scores with background information on the students' or on the teachers' credentials. The issues, as of this writing, are inchoate. Options for resolving them are currently unclear.

Peer-reviewed journals in relevant disciplines are a continuing resource for learning about issues and options discussed briefly above. For instance, *The Journal of Empirical Research on Human Research Ethics* issues articles on confidentiality protection and people's perceptions of it, on informed consent, in the context of privacy and related matters. *The Journal of Official Statistics*, published under the auspices of Statistics Sweden, covers some technical matters as do others. Short courses and workshops developed for researchers are necessary at times to assure that researchers keep abreast of the state of the art in this sector.

Because laws and codes can prevent valuable research, it is essential to understand how and when to balance interests in confidentiality with the potential or actual benefits of research. The advancement of social science knowledge depends on achieving the balance. The latter embodies the challenges and the future prospects.

Abstract

Privacy is a subject that has captured the interest of scholars across a wide range of disciplines resulting in a significant and rich body of literature. Yet despite these efforts we still struggle to understand privacy. It is a nebulous concept with a strong subjective element. There are three central and contested issues which underpin most debates. They are what is the scope of privacy; why do we value privacy; and critiques of privacy. Understanding the complexity of these issues is vital to the development of effective privacy laws.

The Developing Field

Privacy is a subject that has captured the interest of scholars across a wide range of disciplines, resulting in a significant and rich body of literature. Yet despite these efforts we still struggle to understand privacy. It is a nebulous concept with a strong subjective element: we disagree as to when, where, and why we want or need privacy; thus it seems unlikely that there will ever be a universally accepted precise definition of privacy.

Any realistic attempt to understand privacy cannot be limited to purely legal or philosophical 'definitions'. Indeed in 2007 the New Zealand Law Commission noted that "it is regrettable that the concept of privacy has not been treated as multi-disciplinary (encompassing fields of philosophy, political theory, policy studies, historical and cultural studies) as much as it ought to have been in some legal literature" (New Zealand Law Commission, 2007). Whilst there is considerable work still to be done, there is a huge body of cross-disciplinary literature on privacy emerging. Every year numerous conferences bring together researchers from a whole range of disciplines (including economics, computer science, law, philosophy, political science, communication studies, and media studies), as well as policy-makers and practitioners. Such conferences play a key role in facilitating cross-disciplinary discussion as well as comparative and global analysis. This cross-fertilization is crucial. Lawyers cannot operate in a vacuum; they need to know how people behave and why they behave that way, the consequences of interferences with privacy, and the costs of such interferences – the answers to these questions lie beyond the confines of the law. Moreover, modern technology means that the consequences of an interference with privacy may ripple well beyond the boundaries of a particular jurisdiction; for example, where unlawfully obtained photographs are published in overseas publications or on the Internet, such developments raise serious problems for enforcement which render comparative and international research particularly valuable.

Discussions relating to privacy deal with numerous questions, but there are three central and contested issues which underpin most debates. They are what is the scope of privacy; why do we value privacy; and critiques of privacy.

Scope of Privacy

To develop effective privacy laws we need to be able to identify privacy-related interests. Scholars have offered a number of different means of identifying the scope of privacy and privacy-related interests. Traditionally life has been separated into spheres of public life and private life. This is a complex idea that is linked to theories of the proper role of the state. The public/private divide was first used to distinguish between politics which took place in the public sphere and the family which existed in the private sphere – for discussion, see Beate Rössler (2005). The idea that life can be divided into public life and private life is also reflected in privacy scholarship. This separation of public and private spheres emerges in a number of ways. It is found in theories based on private places, private information, and private decisions. Naturally, within each of these models the location of the dividing line between what is public and what is private is contested. Moreover, the very idea that we can distinguish between what is public and what is private is itself heavily contested. Partly as a response to the perceived limitations of these models, broader theories have been developed, which allow for a more subjective element. Rather than simply categorizing interests as 'public' or 'private' these theories have emphasized the subjective nature of privacy, they acknowledge that individuals have different privacy needs and that we do not have universally shared views about what is private and what is not. This sort of approach is often found in access-based models, which are based on the need to be left alone and to control access to ones self. Thus the privacy literature can be broadly categorized into the following types of theories: those that protect private places; those that are based upon managing private information; those that encompass limiting access to self; and those that seek to establish a realm of private decision-making. Scholars may seek to accommodate one or more of these approaches into their conception of privacy. For a critique of these different approaches, see Solove (2002).

One approach is to designate particular locations as private and to identify activities which occur in those places as private and deserving of privacy. This restricts privacy to private spaces. Clearly one of the difficulties with this approach is identifying what constitutes a 'private space'; the home is often regarded as the paradigm private place, but where else is private? A related

objection is that there are some activities which occur in public places which should be regarded as private (Moreham, 2006). Alan Westin identified four types of privacy: solitude, intimacy, anonymity, and reserve; these states of privacy range from experiences of privacy when one is alone to experiences of privacy in public (Westin, 1967). Even if we can identify objectively designated 'private places' the idea that we only seek or experience privacy in those spaces is unrealistic and does not accord with how we behave in practice (Westin, 1967; Altman, 1975; Moreham, 2006; Hughes, 2012).

Decision-making privacy is a model which also derives from the public/private divide and the liberal tradition. Some models of privacy designate the realms of life into which the state should not interfere. This means that there are decisions which one is entitled to take without being dictated to or influenced by the state, and are therefore called decision-making privacy. This type of analysis has been used in the United States where it has developed out of judicial interpretations of the Fourth Amendment, *Olmstead v United States* (1928) 277 US 438; and *Katz v United States* (1967) 389 US 347. For example, in *Griswold v Connecticut* (1965) 381 US 479, the Supreme Court found that prohibiting contraception violated the marital right to privacy and in *Roe v Wade* (1973) 410 US 113, the Supreme Court found that laws prohibiting the right to abortion violated a constitutional right to privacy. Decision-making privacy is attractive for some scholars because privacy becomes a tool for social change. However, decision-making privacy is problematic because it is highly subjective. It may be possible to achieve a degree of consensus within a particular sector of society or within a given society but universal agreement may not be possible. Moreover, even within a society, individuals have different perspectives on the role of the state and on decisions that should be protected as private. It should also be noted that some scholars have suggested that the issues raised by decision-making are more directly related to autonomy than privacy (Gross, 1971; Gavison, 1980).

Coupled with the home, private information is the most readily accepted aspect of privacy. It is generally acknowledged that privacy involves controlling access to, and the use of, private information. The problem is usually not whether private information falls within the scope of privacy per se, but rather what constitutes 'private' information, and when it should be protected. This has become increasingly complex and problematic as new forms of technology have provided numerous ways to obtain, collate, store, and search for information. Information is often designated 'private' by looking at its 'type' or 'form'. Types of information that may be regarded as private include details of an individual's sex life, medical treatment, or salary. Forms of information that may be regarded as private include e-mails, medical records, or diaries. Where things tend to get more tricky is when an individual asserts that other types or forms of information are private because the information is 'personal', meaning that the information relates to an aspect of him or herself that is important to him or her. People reasonably disagree as to what information relates to the individual, and what information it is reasonable to want to withhold. A further problem is determining when information should be protected and when it is no longer private. Can information be considered private after it has been voluntarily published on social networking web sites or blogs? Are the web sites that we browse on the Internet private information? If information has been in the public domain can it be protected as private information in the future? Can public figures expect that their information will be protected as private?

Most of these ideas contribute something useful to the literature. The identification of private places and private information is beneficial as there clearly are some types of information and some places that can usefully be categorized as private. For example, we generally regard our medical records as private. Similarly the home is regarded as the paradigmatic space for privacy and we expect to be able to exclude the state and other people from it , if we so desire. However, these universally shared ideas about privacy do not exhaust our needs for privacy. We are not always concerned with preventing the disclosure of information, nor do we stop needing privacy when we leave our homes. This lacuna is addressed by access-based theories.

The limited capacity of an information-based approach to privacy was highlighted by an example used by Richard Parker (Parker, 1974). Parker described a situation in which an astronaut's bodily functions are monitored by ground control. Parker suggests that even if this technology means that ground control knows exactly what the astronaut is doing, one could still imagine the astronaut switching off the camera whilst he was evacuating feces. Parker suggests that the astronaut's ability has very little effect on his ability to control information about himself, but it would still be a severe loss of privacy if he could not turn off the camera. It is difficult to explain the privacy-related interests which arise in this scenario if one regards privacy as restricted to our interests in controlling access to information. An information-based theory of privacy may seek to explain this example by suggesting that the image of the astronaut evacuating is a form of private information. However, that would involve a dubious use of the term 'private information', which would raise questions about definitional coherency and breadth. More significantly, this type of analysis would neglect the vulnerability of the astronaut. The astronaut's vulnerability stems from the visual element of the intrusion and the feeling of exposure. This sensation is not reflected in an information-based approach to privacy. Nicole Moreham has explored this issue. She suggests that something "less tangible and more 'spiritual' than 'information' is obtained in these situations and an approach based entirely on 'information' therefore fails to accommodate them adequately" (Moreham, 2005).

The difference between information-based approaches and access-based approaches is also crucial when privacy runs up against other competing rights and interests. Privacy often has to be defended against those who argue that "one has nothing to fear if they have nothing to hide"; for a critique of this view, see Solove (2007). Characterizing privacy as a right to control private information renders it vulnerable to these challenges. These debates often involve one party operating on the presumption that the privacy-seeker would only wish to keep information private if the dissemination of that information would have adverse consequences for the privacy-seeker. This presumption is wrong. It assumes that what we are seeking is secrecy and that secrecy is sought to facilitate deception.

However, many of our concerns about privacy have nothing to do with secrecy or deception. We simply wish to have control over our lives. It is not simply that we fear the consequences of exposure. It is that we object to being subjected to the control of others.

Access-based theories recognize that we may legitimately object to activities such as surveillance, even if those activities do not lead to the gathering of harmful information (or in fact any information) and even if they occur in public places. Objections to these types of intrusions do not relate to the private nature of the location, nor do they stem from concerns over protecting the disclosure of private information. This need for privacy is recognized in theories based on controlling access to self; however, those theories have been criticized for their breadth and for their inability to distinguish privacy from other forms of unwanted access.

There are a number of variations of the access-based model. Warren and Brandeis advocated 'the right to be let alone' in an article that has shaped the scope of US privacy law and scholarship (Warren and Brandeis, 1890). Their concerns were triggered by the development of the portable camera and its use by the 'yellow press'. This technological development meant that individuals were vulnerable in ways that they had not been before. Scholars have developed this idea of privacy as the 'right to be let alone' (Allen, 1988; Bok, 1983; Gross, 1967; Van Den Haag, 1971). For example, Ruth Gavison suggests that an invasion of privacy occurs where an individual is subjected to unwanted physical proximity (Gavison, 1980). Nicole Moreham suggests a model based on desired access (Moreham, 2005). These theories of privacy reflect many of our intuitions about privacy. However, there is a danger that we end up with a conception of privacy that is too broad. As Daniel Solove explains "certainly not all access to the self infringes upon privacy, only access relating to specific dimensions of the self or to particular matters and information" (Solove, 2008). Solove is right in that these theories of privacy struggle to identify privacy scenarios. However, it is questionable whether his approach is any better. He has suggested that instead of trying to establish an over-arching theory of privacy, we should identify privacy problems. He has developed a taxonomy which encapsulates the range of privacy problems which have been identified in the existing literature. The taxonomy includes four groups of 'harmful activities': (1) information collection; (2) information processing; (3) information dissemination; and (4) invasion. He breaks down this last category into two types of activities: (1) intrusion; and (2) decisional interference. His description of 'intrusions' describes the type of problems that would emerge from the unwanted access approach. However, Solove offers no means of identifying these 'intrusions'. Hughes suggests that one solution to this problem might be to examine the way in which we experience privacy, and in particular the role that barriers play in establishing privacy, (Hughes, 2012; see also Rickless, 2007; and Altman, 1975).

Value of Privacy

Why do we want to or why should we want to protect privacy? What value or purpose does it serve? The value of privacy is as contested an issue as its scope. The arguments break down to four, sometimes competing and sometimes overlapping, points of view. First there are those that believe that whilst privacy consists of a number of interests, there is nothing special that justifies uniting these interests into a single concept and that privacy is therefore redundant as a concept (reductionist stance); there are others who believe that privacy is underpinned by a single value; still others believe that privacy is underpinned by a cluster of values which benefit the individual; and finally there are those who believe that privacy is beneficial for society.

Judith Jarvis Thomson offered the classic reductionist critique of the right to privacy (Jarvis Thomson, 1975). Reductionist critiques of privacy argue that privacy can be reduced to a number of other interests and that there is no special characteristic that unites these interests. As a result, in any scenario where one might wish to claim a right to privacy, there is actually a more suitable interest or right available and privacy is superfluous. Thomson's argument has been criticized because it requires us to accept the existence of a number of other rights; and a key weakness is her failure to explain why her cluster of rights is preferable to a right to privacy (Scanlon, 1975; Reiman, 1976; Rössler, 2005). Following Thomson's article, a number of scholars sought to respond by identifying 'the' value which underpins privacy. For example Rachels (1975) argued that privacy was essential for intimacy and Reiman (1976) argued that privacy is connected to personhood. However, many of these values appear to have some relationship to privacy, e.g., intimacy, autonomy, dignity, personhood, etc. Thus other theorists have responded to this issue by suggesting that a cluster of values underpins privacy.

Alan Westin identified a cluster of 'functions' of privacy. Those functions were personal autonomy; emotional release; self-evaluation; and limited and protected communication (Westin, 1967). Daniel Solove uses Wittgenstein's family resemblance concept to describe the complexity of privacy and its relationship to a cluster of values (Solove, 2002, 2008). Wittgenstein explained his family resemblance concept by examining the ways in which we use the term 'games'. If we consider different types of games, we see that there is no single characteristic that identifies all games: some use a ball, a board, or pieces; some are played in teams or by individuals; some involve winning or losing; but none of these characteristics is prevalent in all scenarios where we might term something a game (Wittgenstein, 1958). Solove draws upon this idea to argue that the quest for a common denominator leads to greater confusion. Other scholars have also used a cluster approach: see Feldman's human flourishing approach (Feldman, 1994, 1997).

Unlike a number of other rights, for example the right to freedom of expression, privacy has traditionally been seen as an individualistic and even selfish right which affords few (if any) social benefits. A number of scholars have suggested that this approach is too narrow and that the social and group benefits involved in privacy have been rendered invisible as a result. These scholars have highlighted the social value of privacy (Schoeman, 1992; Regan, 1995; Feldman, 1997; Rössler, 2005). The social value of privacy may be harder to comprehend than the social value of other rights and interests; however we need to strive to understand its role.

Critiques of Privacy

Critics call into question the idea that privacy is desirable. They argue that there are other needs and interests which are adversely affected, that the abused child or partner does not want privacy, that in fact what they really want is dignity, autonomy, and freedom from oppression, and that these are the very rights and interests that privacy precludes.

One of the most powerful parts of the literature is the feminist critique of privacy. The feminist critique of privacy highlights the fact that employing concepts such as 'public' and 'private' to identify privacy-related interests is problematic because these concepts are so deeply entrenched in political ideology. These objections are summed up by the feminist slogan 'the personal is political' which reflects the idea that issues which are characterized as 'private' are in fact, and should be seen as, political. This is perhaps most apparent when these concepts are used to claim a sphere of private decision-making, for discussion, see Rössler (2005). Critics claim that the concept of a private life is employed to prevent women from fully engaging in the public sphere and leaves women vulnerable to oppression in the private sphere. These issues are reflected in feminist opposition to the designation of the home as private. Identifying the home as private, shields the home and activities which occur within it from the scrutiny of others, opening up possibilities for domestic violence and other forms of abuse (Allen, 1988; MacKinnon, 1987, 1989; Suk, 2009a,b). Some feminists argue that the private realm is both idealized and undervalued: it is idealized when it is stereotyped as a realm of affection, acceptance, and freedom from pressure; it is undervalued as most of the work conducted in the private realm – child rearing and house work – is unappreciated and is in fact invisible in society (Lacey, 1998). Furthermore, the liberal idea that the private realm is free from state influence is also false as the state often structures private life.

Other scholars have also attacked the value of privacy from a range of perspectives. For example, Amitai Etzioni offers the classic communitarian critique of the right to privacy (Etzioni, 1999). Etzioni does not reject privacy entirely; instead his criticism is targeted at what he perceives as the privileging of privacy over the common good. A further critique of privacy is offered by Richard Posner who has attacked the protection of personal information on the grounds of economic inefficiency (Posner, 1977–78, 1981).

Legal Protection of Privacy

Privacy is protected using a range of different types of laws including criminal law, tort law, data protection laws, constitutional rights, and human rights. Privacy problems may therefore require analysis across a number of different areas of law drawing upon torts, statutory provisions, rights, and regulatory regimes. They may also raise issues across different jurisdictions, for example, where the information is obtained in one jurisdiction and used in another jurisdiction, or where information is published globally.

Privacy laws reflect the broad scope of the concept and may be relevant to a whole range of activities such as stop and search techniques, the use of surveillance technology, the use of DNA and retention of DNA data, access to e-mail and internet usage data, the publication of news stories and photographs, harassment, and the right to contraception or to have an abortion, amongst many others.

The right to privacy receives international recognition under Article 12 of the Universal Declaration of Human Rights, Article 17 of the International Covenant on Civil and Political Rights, and Article 8 of the European Convention on Human Rights (ECHR), which protect the right to respect for private life.

The European Convention on Human Rights is an international treaty which has been ratified by the members of the Council of Europe. Individuals can bring proceedings against their state before the European Court of Human Rights (based in Strasbourg). The Court issues judgments; it can find that the state has violated a Convention right, and it may require the state to pay non-pecuniary damages and costs under just satisfaction.

The Convention does not contain an express right to privacy. Article 8 ECHR protects the right to respect for private life, family life, home, and correspondence. However, as Article 8 ECHR was designed to implement Article 12 of the Universal Declaration of Human Rights (which does refer to privacy), it seems to have been intended that Article 8 ECHR would deal with privacy rights. The Court has also referred to a right to privacy (see, for example, *Armonienė v Lithuania* (App. No. 36 919/02) (2009) 48 EHRR 53); and a number of Parliamentary Assembly resolutions expressly state that Article 8 ECHR guarantees a right of privacy (see, for example, Resolution 1165 (1998) of Parliamentary Assembly of the Council of Europe on the Right to Privacy and Resolution 428 (1970) of Parliamentary Assembly of the Council of Europe a Declaration on Mass Communication Media and Human Right. See also Resolution 1843 (2011) of Parliamentary Assembly of the Council of Europe on the Protection of Privacy and Personal Data on the Internet and Online Media).

Under the Court's Article 8 ECHR jurisprudence, it has held that wiretapping (*Malone v United Kingdom* (1985) 7 EHRR 14); the power to stop and search citizens in the street (*Gillan and Quinton v United Kingdom* (2010) 50 EHRR 45); a state DNA database (*S and Marper v United Kingdom* (2009) 48 EHRR 50); and the installation of a GPS tracking device to a suspect's car, engage the right to privacy (*Uzun v Germany* (2011) 53 EHRR 24). The right to privacy is not absolute under the Convention, thus even where the right is engaged the Court will then have to consider whether the interference may be justified under Article 8(2) ECHR. Under that provision, an interference is justified if the interference is prescribed by law, is in pursuit of a legitimate aim, and is necessary in a democratic society. The legitimate aims are set out in the text of the Convention right itself as follows: national security, public safety, or the economic well-being of the country, for the prevention of disorder or crime, for the protection of health or morals, or for the protection of the rights and freedoms of others.

Article 8 ECHR also affects the protection afforded by the state when the intruder is a private individual or organization. Thus the European Court of Human Rights has held that the state failed to protect privacy where a magazine published photographs of the applicant (see *Von Hannover v Germany* (2005) 40 EHRR 1) and where a photographer took photographs of a child without the child's parents' consent (see

Reklos and Davourlis v Greece [2009] EMLR 16). It should be noted though that in these cases the European Court of Human Rights, and the domestic courts will have to balance Article 8 ECHR against Article 10 ECHR (the right to freedom of expression). The European Court of Human Rights has laid out a set of criteria for striking an appropriate balance between those two rights in *Von Hannover v Germany* (*No. 2*) (2012) 55 EHRR 15 and *Axel Springer Germany* (2012) 55 EHRR 6. Those criteria are as follows: (1) whether the publication contributes to a debate of general interest; (2) how well known is the person concerned and what is the subject of the report; (3) prior conduct of the person concerned; (4) content, form, and consequences of the publication; and (5) the circumstances in which the photographs were taken.

In the United States privacy has received protection by virtue of a number of provisions, including the Fourth Amendment and the Fourteenth Amendment, as well as a number of privacy torts: the American Law Institute Restatement of Torts followed Prossers classification of four privacy torts, Prosser (1960). Section 8 of the Canadian Charter of Rights and Freedoms has a remit similar to the United States Fourth Amendment. Most Western countries offer some protection to privacy whether it is in the form of constitutional or human rights or through other legal regimes.

One of the key tools in privacy law is the reasonable expectation of privacy test. The reasonable expectation of privacy test was first developed in the United States in the landmark Fourth Amendment phone tapping case – *Katz v United States* (1967). Since *Katz* the test has been the touchstone for Fourth Amendment jurisprudence. In Canada the test is used in Section 8 of the Canadian Charter of Rights and Fundamental Freedoms jurisprudence. The test has also been used in the jurisprudence of the European Court of Human Rights as well as the English law of misuse of private information. The test is used in different contexts in different jurisdictions (Hughes, 2012) and its capacity to deal with the problems that we face is contested (Solove, 2010; Kerr, 2007, 2008; Hughes, 2012).

One of the biggest differences between legal regimes is the balance struck between privacy and competing rights and interests, in particular the right to freedom of expression. Whilst the United States provides strong protection to freedom of expression as a result of the First Amendment, the European Convention on Human Rights and a number of European countries such as the United Kingdom, Germany, and France offer a more balanced approach to the two rights. The tension between these two rights most often arises in a media context, and in particular when deciding whether an injunction should be issued to restrict the publication of a news story, which contains private information or photographs.

Many jurisdictions currently face a number of key challenges including, how to respond to new technology which provides novel means of interfering with privacy, whether legal regimes should be based on an opt-in or opt-out model, to what extent individuals, and in particular children, should be allowed to waive their right to privacy, and how to enforce legal protection in the digital world, particularly against anonymous intruders. To address these concerns we will need to return to the difficult questions examined by privacy theory. Moreover we will need to consider whether existing conceptions of privacy provide us with the necessary tools to address current and future problems or whether these challenges necessitate a reconsideration of how we conceptualize privacy.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Proactive Interference

Ian Neath and Aimée M Surprenant, Memorial University of Newfoundland, St. John's, NL, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Proactive interference (PI) is when something learned earlier impairs the ability to remember something learned more recently. PI can be observed in all subject populations and in all memory systems, including the perceptual representation system, procedural memory, semantic memory, long-term episodic memory, and short-term/working memory. One current theoretical account of PI attributes its cause to cue overload: the more items a cue subsumes, the less effective the cue will be. Other accounts suggest that items learned earlier can reduce the distinctiveness of current items, making successful retrieval less likely.

Proactive interference (PI) occurs when something learned earlier impairs a person's ability to remember something learned more recently. For example, if you change phone numbers, memory for your previous number can make remembering your new number more difficult. A related phenomenon, retroactive interference, is similar except that it is when something learned recently impairs a person's ability to remember something learned earlier. For example, learning your new telephone number can make remembering your previous number more difficult.

Historical Overview

PI has been well known since the beginnings of scientific research on memory. For example, in 1889, Hugo Münsterberg described an example based on his own observations after changing the pocket in which he carried his watch. When asked for the time, he would reach in the old pocket for the watch, not the new pocket. In 1894, Müller and Schumann formally defined PI as follows: "When any two items, as *A* and *B*, have been associated, it is more difficult to form an association between either and third item, *K*" (McGeoch, 1942: p. 402).

The Müller-Schumann Law of Associative Inhibition received substantial empirical support as part of what became known as Interference Theory (for a review of the theory and supporting data, see Crowder, 1976; *see also* Retroactive Interference). The prototypical design is outlined in Table 1 and has two phases each of which uses paired associates learning. In this task, the subject is asked to learn a particular novel pairing of two stimuli, such as two nonsense words or two real words. For example, in Phase I, a person might see the word pairs DOG-ROOF, CAR-DESK, HOUSE-MUG, and so on. The stimuli in Phase I are often represented by the term A-B, with A standing for the first item, or cue, and B standing for the second item, or target. At test, the subjects are given the first item (A) and are asked to provide the second item (B). PI is observed in Phase II, when people are asked to learn more items. The control group is asked to learn a second list that contains entirely new items, such as PHONE-COFFEE, LAMP-WALL, referred to as C-D pairs. The use of the letters C and D indicate that the lists are different from those in Phase I. The experimental group is asked to learn a list that reuses the A items but pairs them with new, D, items such as DOG-COFEE, CAR-WALL. Note that in Phase I, DOG was paired with ROOF but in Phase II, DOG is now paired with COFFEE. At test, the experimental group does worse than the control group because the B items studied in Phase I interfere with memory for the D items in Phase II.

Table 1 A typical AB–AD design to produce proactive interference (PI). Recall of the D items is worse in the experimental group than in the control group

Group	*Time 1*	*Time 2*	*Test*
Control	A–B	C–D	C–D
Experimental	A–B	A–D	A–D

Of course, PI can be observed in more simple designs, as noted by Underwood (1957). He pointed out that in most memory experiments, subjects are given a list, are asked to recall it, and are then given another list, which they recall; this sequence is repeated many times. What if we were to plot percent correct on a single list, as opposed to averaged over lists, and also indicate how many previous lists had been experienced? Figure 1 reproduces his results based on numerous studies: As the number of prior lists increased, the level of recall decreased. (In Underwood's (1957) original figure, each study was plotted separately. In the figure shown here, when there are two or more studies for a particular number of previous lists, the mean of those values is used.)

PI and Multiple Memory Systems

Currently, the dominant theoretical account of memory divides it into multiple different systems, with the most popular formulation being the five memory systems described by Tulving and his colleagues (e.g., Tulving, 1985; for a review, see Surprenant and Neath, 2009). These are often further classified as either nondeclarative memory systems (the perceptual representation system and procedural memory) or declarative memory systems (semantic, episodic, and short-term/working memory). Although there is no question that PI is observable in the first four of the hypothesized memory systems, there is substantial disagreement about whether it occurs in certain

Figure 1 Proportion correct recall of a list of items as a function of the number of previous trials. The data points are from Underwood (1957), the line shows the prediction of the model SIMPLE, described below. Source: Brown, G.D.A., Neath, I., Chater, N., 2007. A temporal ratio model of memory. Psychological Review 114, 539–576. Adapted with permission of APA.

types of working memory. Below we describe representative studies that demonstrate PI in each memory system in turn.

PI and Nondeclarative Memory

The first major division of memory is between nondeclarative Non declarative (procedural) memory and declarative memory systems. The former is concerned with knowing 'how' to do something (for example, how to ride a bicycle), whereas the latter is concerned with knowing 'that' something is the case (for example, that George Washington was the first president of the United States). There are two types of nondeclarative memory, the perceptual representation system and procedural memory. PI can be observed in both.

PI in the Perceptual Representation System

The perceptual representation system consists of a collection of domain-specific modules that operate on perceptual information about the form and structure of words and objects. Much of the data used to argue for the existence of the perceptual representation system as a separate memory system comes from studies of priming, in which certain stimuli are seen at Time 1 and then their influence is measured by subsequent performance at Time 2. Importantly, the typical task uses incidental learning (there is usually a cover task so that the subject is unaware that there will be a later or subsequent test of the material) and also uses indirect measures of memory (there is no direct mention that the test is related to the learning episode). This type of memory is often referred to as implicit memory (*see* Implicit Memory).

Lustig and Hasher (2001) demonstrated PI using a word-fragment completion task, a task commonly used to evaluate the perceptual representation system. The baseline group of subjects saw word fragments, such as *a _ l _ _ g y*, and were asked to complete them to form a valid word. This provides a baseline of how many times a particular fragment was completed with a particular word. There were two additional groups, both of which participated in two phases. In Phase I, the subjects saw a list of words and were asked to indicate the number of vowels that occurred in each word. This task induces processing of individual letters, but is unlikely to induce the subjects to actively memorize the stimuli for a subsequent test. There was then a pause, during which several additional tasks unrelated to the experiment occurred. The purpose was to make it less likely that the subjects would link Phase I and Phase II. Finally, in Phase II, the key tests were presented. Both experimental groups received word fragments and were asked to complete them. The difference between the interference and noninterference groups was the relation between the fragments shown at test and the words seen earlier in Phase I. For example, the noninterference group might receive the word fragment *a _ l _ _ g y* at test, and would also have seen the word *allergy* in the original list. The interference group also saw *allergy* in the original list, but in addition, they saw a potentially interfering word such as *analogy*. Although both groups showed priming (they completed the fragment more often than the baseline group), there was less priming in the interference condition than in the noninterference condition.

It should be noted that the stimuli need not necessarily be verbal in order to observe PI in the perceptual representation system; for example, Köster et al. (2002) demonstrated PI in implicit memory for odors.

PI in Procedural Memory

Procedural memory is a memory system responsible for basic associations, motor learning, and simple cognitive skills. PI is easily demonstrated in tasks thought to tap this system. For example, Cook (1941) used a mirror drawing task in which the subject is asked to trace a shape shown in a mirror. One block of trials had the mirror reflecting one way, whereas the second block of trials changed the reflection. Cook found that after practicing five trials, performance (in terms of accuracy) dropped substantially when the mirror was changed. Similar results have been found for other motor skills. One of the more notable is the study by Fitts and Jones (1961) analyzing crashes in World War II aircraft. They found that accidents were especially likely when pilots switched between the B-25, C-47, and C-82 aircraft due to differences in the motor movements needed to operate the aircraft.

Declarative Memory

Declarative memory is divided into two major types, semantic memory (*see* Semantic Memory) and episodic memory (*see* Episodic Memory). One key distinction between these two systems is whether the remembering person is aware of the learning episode. For example, many people know that George Washington was the first president of the United States, but they are unaware of when they learned this and are unaware of any other details from the learning episode. In contrast, when people recall a list of words immediately after hearing them, they are fully aware of the episode in which the target items were experienced. In contrast to semantic memory, then, "episodic memory affords the additional capability of acquisition and retention of knowledge about personally experienced events and their temporal relations in subjective time and the ability to mentally 'travel back' in time" (Tulving, 1985: p. 387). Episodic memory is further divided into long-term and short-term (or working) memory.

PI in Semantic Memory

There is a very large volume of literature showing that information in semantic memory can cause PI in a wide range of tasks. For example, Waszak et al. (2004) asked subjects to alternate between a word-reading task and a picture-naming task. In the picture-naming task, the subject saw a word printed on a picture, such as the word *throat* printed on a picture of a foot, and was asked to say the name of the picture; in this example the response would be *foot*. Then, three different word-reading tasks could follow. The key here is that there were two types of priming: identity priming (i.e., the item itself, similar to the priming discussed in the perceptual representation system example with word fragment completion) and semantic priming (i.e., a related item, in which responses to the word *doctor* are faster if the word *nurse* has been processed previously). In one condition, the task featured the same stimuli and therefore invoked only identity priming (but keep in mind the subject would now be asked to respond with the word, i.e., *throat* rather than the name of the picture *foot*). The second condition had only semantic priming; for example, the word *thumb* printed on a picture of a leg. The third condition had novel items, such as the word *ship* printed on an airplane, which involves neither identity nor semantic priming. The main variable of interest was how long it took to read the word following a switch from the picture-naming task. Waszak et al. (2004) found that it took longer to read the word *thumb* when the prior trial consisted of naming a picture of a foot than when the prior trial was naming a picture of an airplane. That is, PI occurred because a semantically related item on an earlier trial interfered with the ability to read a word on the next trial.

One area of particular interest is the effect of prior knowledge on the acquisition of new knowledge. For example, people have experienced PI when moving from one type of problem and then trying to solve a second one (Luchins, 1942), when moving from one text editor to another (Singley and Anderson, 1989), and when learning a second language (MacWhinney, 2005). Roediger and Neely (1982) describe a number of additional cases of what they term 'retrieval blocks' in semantic memory; in each, the block can be attributed to the role of prior information or PI.

PI in Long-term Episodic Memory

Most laboratory-based studies use episodic tasks: a series of items are presented, and then a test session occurs in which memory for the just-presented information is assessed. Episodic memory has often been subdivided into long-term and short-term memory. PI is readily observed in long-term memory. For example, Greenberg and Underwood (1950) had subjects learn lists on four successive days; on each day, the subjects first recalled the list learned the previous day. It is this 24-h retention interval that makes it a test of long-term memory. With no prior lists, the mean percent correct was approximately 70%, but with three prior lists, performance dropped to approximately 25% correct.

The other type of episodic memory is variously known as short-term or working memory (*see* Short Term Memories, Theories of). There has been considerable debate over whether PI occurs in this system. It is worthwhile taking the time to examine how the debate has changed over the years, as the question is intimately related to the issue of what causes forgetting.

PI in Short-term/Working Memory

Does PI occur in short-term memory? The question originated with the first studies on short-term memory and concentrated on two main areas, the Brown–Peterson paradigm and investigations into a subsystem of working memory called the focus of attention.

PI in the Brown–Peterson Paradigm

In the Brown–Peterson paradigm (named after two sets of researchers who independently developed the task), the subject hears or sees a stimulus (e.g., three consonants in a row, such as DBX), and is then given a 3-digit number. The subject's task is to count backward by 3 (or 4 or 7) from the 3-digit number for a certain amount of time. At the end of this period, the subject is asked to recall the three consonants in order. The purpose of

counting backward is to prevent rehearsal while minimizing overt interference: the digits are sufficiently different from the letters that they should not interfere. The number of items to recall is small enough that capacity limits should not be a problem. The main results of interest are shown in Figure 2: Peterson and Peterson (1959) varied how long the subjects counted backward, including conditions of 3, 6, 9, 12, 15, and 18 s. What is most noteworthy is that after as little as 18 s of counting backward, subjects could recall only about 10% of the items.

This result has been replicated a large number of times, and was initially described as showing the rapid loss of information in short-term memory due to decay. However, a number of studies quickly questioned this conclusion.

Underwood (1957) had shown that recall decreases as the number of prior lists increase. What happens if performance on the first trial of a Brown–Peterson task is examined? Keppel and Underwood (1962) did just this and found no difference in forgetting on the first trial as a function of distractor duration. That is, it did not matter whether the subject counted backward for 3 s or for 30 s, the performance was equivalent. Differences as a function of the distractor duration appeared only on subsequent trials, a finding consistent with the idea that PI builds up over trials. This result has been replicated a number of times (see Crowder, 1976; for a review).

Wickens et al. (1963) came up with a simple test of the interference account. If PI builds up over trials because similar stimuli are used on each trial, changing the type of stimuli should release the subject from the negative effects of PI. To test this idea, the researchers presented consonants on the first three trials; on the fourth trial, they presented numbers. Because numbers were now being used as to-be-remembered stimuli, a different distractor task was used: naming colors. As shown in Table 2, there were actually four groups: one switched from letters to numbers, another switched from numbers to letters, a third had only letters on all four trials, and the fourth had only numbers on all four trials. Performance in the switched groups was much better on the fourth trial than in the control groups. This effect became known as the build-up and release from PI, and has also been replicated numerous times with many different kinds of stimuli. For example, build-up and release from PI can be observed when changing taxonomic category, presentation modality, or even part of speech. One particularly interesting release concerns what is known as the semantic differential. If all the words on the first three trials have similar meanings, such as something pleasant (sunny, enjoy, happy), but the words on the last trial mean something different (kill, death, illness), PI will build up and then be released. Crowder (1976) provides a summary of much of this literature.

Build-up and release from PI has also been observed with stimuli including television news (Gunter et al., 1980); prose passages (Blumenthal and Robbins, 1977); and motor learning tasks (Dickinson and Higgins, 1977). Dempster (1985) has shown PI can build up in situations like those encountered with standard academic tests, and Bunting (2006) has observed PI in measures typically used to assess and predict cognitive performance, including intelligence.

Note that the decay view initially proposed as the cause of forgetting in this situation has two difficulties accounting for the data. First, why is performance equivalent on the first trial regardless of whether the delay is 3 or 30 s? Second, why does performance improve on the fourth trial in switched group when the delay is exactly the same as in the unswitched group? Forgetting in the Brown–Peterson paradigm, then, is best accounted for by PI rather than decay.

Figure 2 The proportion of trigrams correctly recalled as a function of the duration of the distractor task. The data points are from Peterson and Peterson (1959), the line shows the prediction of the model SIMPLE, described below. Source: Brown, G.D.A., Neath, I., Chater, N., 2007. A temporal ratio model of memory. Psychological Review 114, 539–576. Adapted with permission of APA.

Table 2 Design to show build-up and release of PI. The two control groups will show decreasing performance over all four trials. The two experimental groups will show decreasing performance through Trial 3, but will show enhanced performance on Trial 4

Group	*Trial 1*	*Trial 2*	*Trial 3*	*Trial 4*
Control 1	Digits	Digits	Digits	Digits
Experimental 1	Digits	Digits	Digits	Letters
Control 2	Letters	Letters	Letters	Letters
Experimental 2	Letters	Letters	Letters	Digits

PI in the Focus of Attention

There is another form of temporary storage that is held to be immune from PI, and it is usually referred to as the focus of attention. In most theoretical accounts of working memory, the focus of attention is exactly what it sounds like: it contains those items that are currently the focus of attention and, crucially, its capacity is very limited. The maximum number of items that can simultaneously be held in the focus of attention is approximately 3–4 (see Cowan, 2000). The prediction is that in general, tasks with fewer than four items will not show PI because those items can all fit in the focus of attention. However, tasks with more than four items will show PI, because in addition to the focus of attention, other parts of short-term or working memory are needed to retain the items.

Consistent with this view, there are a large number of studies that have failed to find PI with short lists but have observed PI with longer lists. The typical study manipulates semantic similarity. For example, on Trial 1, four items are shown, followed by a target item. The subject's task is to indicate whether the target was one of the items just seen. Usually, performance is close to perfect, so the main variable of interest is response time. On Trial 2, items from the same semantic category are used again. For example, Trial 1 might have four types of metal, and Trial 2 might have four additional types of metal. At some point, the category changes; for example, it might change from types of metal to types of vegetables. In studies that use lists with six or more items on each trial, PI builds up; that is, response time to correctly determine whether the target was on the list increases. When a category change occurs, response time decreases. In contrast, in studies that use lists of only four items, there is no evidence of PI (Halford et al., 1988).

One problem with this type of study is that it may be the case that people do not process items in terms of their meaning if there are very few items to remember. For example, for a list of only three items, it might be more economical (cognitively speaking) to just repeat the items over and over. If this is the case, then one can make the following prediction: If people are doing more superficial processing with shorter lists than with longer lists, PI should be observable on the shorter lists if the potentially interfering item is similar on the more superficial level. That is, PI will be seen if the type of items is similar. For example, if the first few trials all use digits, then PI should build up. A number of studies have confirmed this prediction. For example, if the first few trials each have three digits, but at some point the type of stimuli changes to letters, build-up and release of PI is observed even though the number of to-be-remembered items is less than the presumed capacity of the focus of attention (see Surprenant and Neath, 2009).

PI has also been observed in other tasks that also tap the focus of attention. For example, Ruusuvirta et al. (2008) used a two-tone pitch comparison task in which the subject was asked to judge whether the second tone was lower, the same as, or higher in pitch than the first tone. Given that there are only two items, it is difficult to argue that the capacity of the focus of attention has been exceeded. Nonetheless, PI was observed.

PI in Different Populations

A detailed account of PI in all potential populations is beyond the scope of the current article. However, it is clear that PI has been observed in all populations where it has been directly tested. For example, children typically show more PI than adults, with PI decreasing during late child development (Kail, 2002). Older adults (*see* Aging and Memory) also show PI, with some data indicating that PI increases for older adults as compared with younger adults (Bowles and Salthouse, 2003). Another intriguing finding concerns amnesia (*see* Amnesia: General): By definition, patients with amnesia have difficulty remembering information. There is evidence, however, that some patients with amnesia have memory difficulties because they cannot forget: in at least some cases, they are suffering from massive PI (Hamilton and Martin, 2007).

Theoretical Accounts of PI

Most explanations of PI are very similar to the description of the basic phenomenon: earlier items interfere with memory for later or subsequent items (e.g., Brown et al., 2007; Henson, 1998; Mensink and Raaijmakers, 1988). The differences between the various accounts have to do with exactly how the earlier items are processed at the time of test. Initially, Interference Theory attributed PI to response competition; Crowder (1976) provides a detailed review of the data that first supported and then challenged this account. Here, we focus on current theoretical accounts.

A Cue-Overload Account of PI

One explanation of PI invokes cue overload (Watkins and Watkins, 1975). Cue overload refers to the finding that the more items a cue subsumes, the less effective the cue will be and has been used as an explanation for a number of different memory effects including the list length effect, the fan effect, and even levels of processing (see Surprenant and Neath, 2009; for a review). According to a cue overload interpretation, the category of the to-be-remembered items can be a significant retrieval cue. It is as if the subject were asking at test, 'What were the three letters I just saw?' As more trials occur, the number of potential responses increases. The cue, in this case, letters, becomes less and less helpful, as there are more and more letters to choose from. The number of items subsumed under the category name increases and

performance decreases. When the type of category changes, as in the build-up and release of PI studies, a new cue is used that subsumes fewer items and thus performance improves. It is as if the subject were now asking at test, 'What were the three digits I just saw?' Note that this explanation is not necessarily incompatible with the distinctiveness account outlined below.

A Discrimination Account of PI

Baddeley (1976) offered an explanation for PI based on distinctiveness, and the idea is easy to appreciate through an analogy with visual perception. If you are looking at a set of evenly spaced telephone poles, the closer poles are easy to distinguish from one another, but as the poles get further away from the viewer, the poles start to blend together. This idea was originally developed by Koffka in 1935, and has been invoked by a number of different theorists (see Surprenant and Neath, 2009).

Baddeley's (1976) focus was on the build-up and release of PI in the Brown-Peterson paradigm. Imagine four groups of subjects in a standard Brown-Peterson task. All groups receive the to-be-remembered stimuli, and are then asked to count backward for 9 s. The difference between the groups is how much time elapses between the end of one trial and the beginning of the next trial; this is known as the intertrial interval. For the 0 s group, the next trial starts immediately, so they have a 0 s intertrial interval. For the 15 s group, the next trial starts 15 s after the end of the first, so the intertrial interval is 15 s. The final two groups have intertrial intervals of 30 and 60 s. Loess and Waugh (1967) found that the longer the intertrial interval, the better performance, going from .41 to .47 to .52 to .57 for the 0, 15, 30, and 60 s groups, respectively. (In a second experiment, they included an intertrial interval of 2 min, and did not observe any PI at all.) Assuming it took approximately 20 s to conduct one trial (9 s to present the to-be-remembered items and just over 10 s allowed for recall), we can represent the sequence of events graphically, as shown in Figure 3. Relatively speaking, the four dots representing the four trials are easier to discriminate from one another in the 60 s intertrial interval group (the bottom dots) than in the 0 s intertrial interval group (the upper dots). If this account is correct, then it makes an interesting prediction, outlined below.

Baddeley (1976) suggested that it is not the absolute amount of time but rather the relative amount of time that is important and calculated a ratio that predicts performance levels. To illustrate his ratio, consider another Brown-Peterson experiment reported by Turvey et al. (1970). For ease of exposition, we focus on three of the conditions, which differed only in how long the subjects performed the distracting activity, and we ignore the time taken to recall. One group of subjects counted backward for 10 s, one for 15 s, and one for 20 s. PI built up over trials, as would be expected. On the fifth trial, Turvey and associates had every group perform the distracting activity for 15 s; thus, one group's retention interval increased, one group's remained the same, and the third group's retention interval decreased. What Turvey and colleagues found was the three groups performed differently: On this fifth trial, the 10 s group got worse than on the fourth trial, the 15 s group stayed the same, and the 20 s group got better! Note once again that this pattern is inconsistent with a decay explanation: the same delay does not result in the same level of performance.

Figure 3 Representation of four conditions in the Loess and Waugh (1967) experiment. Each dot represents a complete Brown-Peterson trial and the gaps between the dots show the duration of the intertrial interval.

Baddeley (1976) offered an explanation that builds on the ideas in Figure 4. To simplify a little, we focus on Trial 4 versus Trial 5. The time of presentation of the to-be-remembered items on Trial 4 is represented as P4, and is set as an arbitrary zero point in Table 3. For the 10 s group, retrieval of the items occurs after 10 s (not shown in the table), and this is followed by presentation of the to-be-remembered item on Trial 5 after 10 s, which is represented as P5. Because this is Trial 5, the retrieval attempt is made 15 s later, so R5 occurs at the 25 s marker in the table below. For the 15 and 20 s groups, the same details are shown, but note how P5 for each group occurs later than for the 10 s group. The last column in the table shows what Baddeley called the 'Discrimination Ratio' which is the time between presentation of the fourth item and presentation of the fifth item (the numerator), and the time between presentation of the fifth item and recall of the fifth item (the denominator). For the three conditions, the ratios are 10/15 or .67; 15/15 or 1.00; and 20/15 or 1.33. As the ratio increases, recall increases even though the time to remember the item is identical.

A Distinctiveness Account of PI

The idea described above has been expanded and incorporated into a relative distinctiveness model of memory called Scale Independent Memory, Perception, and Learning or SIMPLE (Brown et al., 2007; *see also* Temporal Distinctiveness Models of Memory). In SIMPLE, items are assumed to be represented as points along a dimension (or as points in multidimensional space). In episodic tasks, the main dimension is temporal with the zero point being the time of recall. The temporal values undergo a log transformation, and then a value is calculated for each item indicating how similar it is to every other item. Importantly, closer neighbors have a larger effect than more distant neighbors. When additional items for

Figure 4 Idealized results showing the build-up of PI and, in the experimental condition, the release from PI when the type of to-be-remembered information is changed.

Table 3 Illustration of how to calculate Baddeley's (1976) discrimination ratio: Later items that are separated more from earlier items will have a larger ratio and a smaller effect of PI

Group	*0*	*5*	*10*	*15*	*20*	*25*	*30*	*35*	*P4–P5*	*P5–R5*	*Ratio*
10	P4		P5			R5			10	15	.667
15	P4			P5			R5		15	15	1.000
20	P4				P5			R5	20	15	1.333

previous lists are similar, the relative distinctiveness of the correct item decreases, other factors being equal. If items differ on two dimensions (e.g., time and semantic), the effects of PI are diminished because the second dimension allows for more accurate discrimination. Brown et al. (2007) describe in detail how SIMPLE produces the lines shown in Figures 1, 2, and 4. Although SIMPLE has not been applied to nondeclarative memory, a similar type of explanation can be advanced.

Abstract

Formal grammars are widely used in speech recognition, language translation, and language understanding systems. Grammars rich enough to accommodate natural language generate multiple interpretations of typical sentences. These ambiguities are a fundamental challenge to practical application. Grammars can be equipped with probability distributions, and the various parameters of these distributions can be estimated from data (e.g., acoustic representations of spoken words or a corpus of hand-parsed sentences). The resulting probabilistic grammars help to interpret spoken or written language unambiguously. This article reviews the main classes of probabilistic grammars and points to some active areas of research.

Introduction

Natural language processing is the use of computers for processing natural language text or speech. Machine translation (the automatic translation of text or speech from one language to another) began with the very earliest computers (Kay et al. 1994). Natural language interfaces permit computers to interact with humans using natural language, for example, to query databases. Coupled with speech recognition and speech synthesis, these capabilities will become more important with the growing popularity of portable computers that lack keyboards and large display screens. Other applications include spell and grammar checking and document summarization. Applications outside of natural language include compilers, which translate source code into lower-level machine code, and computer vision (Fu 1974, 1982).

Most natural language processing systems are based on formal grammars. The development and study of formal grammars is known as computational linguistics. A *grammar* is a description of a language; usually it identifies the sentences of the language and provides descriptions of them, for example, by defining the phrases of a sentence, their interrelationships, and perhaps also aspects of their meanings. *Parsing* is the process of recovering a sentence's description from its words, while *generation* is the process of translating a meaning or some other part of a sentence's description into a grammatical or well-formed sentence. Parsing and generation are major research topics in their own right. Evidently, human use of language involves some kind of parsing and generation process, as do many natural language processing applications. For example, a machine translation program may parse an input language sentence into a (partial) representation of its meaning, and then generate an output language sentence from that representation.

Modern computational linguistics began with Chomsky (1957), and was initially dominated by the study of his 'transformational' grammars. These grammars involved two levels of analyses, a 'deep structure' meant to capture more-or-less simply the meaning of a sentence, and a 'surface structure' which reflects the actual way in which the sentence was constructed. The deep structure might be a clause in the active voice, 'Sandy saw Sam,' whereas the surface structure might involve the more complex passive voice, 'Sam was seen by Sandy.'

Transformational grammars are computationally complex, and in the 1980s several linguists came to the conclusion that much simpler kinds of grammars could describe most syntactic phenomena, developing Generalized Phrase-Structure Grammars (Gazdar et al. 1985) and Unification-based Grammars (Kaplan and Bresnan 1982, Pollard and Sag 1987, Shieber 1986). These grammars generate surface structures directly; there is no separate deep structure and therefore no transformations. These kinds of grammars can provide very detailed syntactic and semantic analyses of sentences, but even today there are no comprehensive grammars of this kind that fully accommodate English or any other natural language.

Natural language processing using handcrafted grammars suffers from two major drawbacks. First, the syntactic coverage offered by any available grammar is incomplete, reflecting both our lack of understanding of even relatively frequently occuring syntactic constructions and the organizational difficulty of manually constructing any artifact as complex as a grammar of a natural language. Second, such grammars almost always permit a large number of *spurious ambiguities*, that is, parses which are permitted by the rules of syntax but have unusual or unlikely semantic interpretations. For example, in the sentence 'I saw the boat with the telescope,' the prepositional phrase 'with the telescope' is most easily interpreted as the instrument used in seeing, while in 'I saw the policeman with the rifle,' the prepositional phrase usually receives a different interpretation in which the policeman has the rifle. Note that the corresponding alternative interpretation is marginally accessible for each of these sentences: in the first sentence one can imagine that the telescope is on the boat, and in the second, that the rifle (say, with a viewing scope) was used to view the policeman.

In effect, there is a dilemma of coverage. A grammar rich enough to accommodate natural language, including rare and sometimes even 'ungrammatical' constructions, fails to distinguish natural from unnatural interpretations. But a grammar sufficiently restricted so as to exclude what is unnatural fails to accommodate the scope of real language. These observations

led, in the 1980s, to a growing interest in stochastic approaches to natural language, particularly to speech. Stochastic grammars became the basis of speech recognition systems by outperforming the best of the systems based on deterministic handcrafted grammars. Largely inspired by these successes, computational linguists began applying stochastic approaches to other natural language processing applications. Usually, the architecture of such a stochastic model is specified manually, while the model's parameters are estimated from a *training corpus*, that is, a large representative sample of sentences.

As explained in the body of this article, stochastic approaches replace the binary distinctions (grammatical vs. ungrammatical) of nonstochastic approaches with probability distributions. This provides a way of dealing with the two drawbacks of nonstochastic approaches. Ill-formed alternatives can be characterized as extremely low probability rather than ruled out as impossible, so even ungrammatical strings can be provided with an interpretation. Similarly, a stochastic model of possible interpretations of a sentence provides a method for distinguishing more plausible interpretations from less plausible ones.

The introduction sets out formally various classes of grammars and languages. Probabilistic grammars are introduced in Section Grammars and Languages, along with the basic issues of parametric representation, inference, and computation.

Grammars and Languages

The formal framework, whether used in a transformational grammar, a generalized phrase-structure grammar, or a more traditionally styled context-free grammar, is due to Chomsky (1957) and his co-workers. This section presents a brief introduction to this framework. But for a thorough (and very readable) presentation we highly recommend the book by Hopcroft and Ullman (1979).

The concept and notation of a formal grammar is perhaps best introduced by an example:

Example 1: Define a *grammar*, G_1, by $G_1 = (T_1, N_1, S, R_1)$, where $T_1 = \{\text{grows, rice, wheat}\}$ is a set of words (a 'lexicon'), $N_1 = \{\text{S, NP, VP}\}$ is a set of symbols representing grammatically meaningful strings of words, such as clauses or parts of speech (e.g., S for 'Sentence,' NP for 'Noun Phrase,' VP for 'Verb Phrase'), and $R_1 = \{\text{S} \rightarrow \text{NP VP, NP} \rightarrow \text{rice, NP} \rightarrow \text{wheat, VP} \rightarrow \text{grows}\}$ is a collection of rules for rewriting, or instantiating, the symbols in N_1. Informally, the nonterminal S rewrites to sentences or clauses, NP rewrites to noun phrases and VP rewrites to verb phrases. The *language*, L_{G_1}, generated by G_1 is the set of strings of words that are reachable from S through the rewrite rules in R_1. In this example, $L_{G_1} = \{\text{rice grows, wheat grows}\}$, derived by $\text{S} \Rightarrow \text{NP VP} \Rightarrow \text{rice VP} \Rightarrow \text{rice grows}$, and $\text{S} \Rightarrow \text{NP VP} \Rightarrow \text{wheat VP} \Rightarrow \text{wheat grows}$.

More generally, if T is a finite set of symbols, let T^* be the set of all strings (i.e., finite sequences) of symbols of T, including the empty string, and let T^+ be the set of all nonempty strings of symbols of T. A language is a subset of T^*. A *rewrite grammar* G is a quadruple $G = (T, N, S, R)$, where T and N are disjoint finite sets of symbols (called the *terminal* and *nonterminal* symbols respectively), $S \in N$ is a distinguished nonterminal called the *start* or *sentence symbol*, and R is a finite set of productions. A *production* is a pair (α, β) where $\alpha \in N^+$ and $\beta \in (N \cup T)^*$; productions are usually written $\alpha \rightarrow \beta$. Productions of the form $\alpha \rightarrow \varepsilon$, where ε is the empty string, are called *epsilon productions*. This entry restricts attention to grammars without epsilon productions, that is, $\beta \in (N \cup T)^+$, as this simplifies the mathematics considerably.

A rewrite grammar G defines a *rewriting relation* $\Rightarrow_G \subseteq (N \cup T)^* \times (N \cup T)^*$ over pairs of strings consisting of terminals and nonterminals as follows: $\beta A \gamma \Rightarrow \beta \alpha \gamma$ iff $A \rightarrow \alpha \in R$ and $\beta, \gamma \in (N \cup T)^*$ (the subscript G is dropped when clear from the context). The reflexive, transitive closure of $\Rightarrow$ is denoted $\Rightarrow^*$. Thus $\Rightarrow^*$ is the rewriting relation using arbitrary finite sequences of productions. (It is called 'reflexive' because the identity rewrite, $\alpha \Rightarrow \alpha$, is included.) The language generated by G, denoted L_G, is the set of all strings $w \in T^+$ such that $S \Rightarrow^* w$.

Rewrite grammars are traditionally classified by the shapes of their productions. $G = (T, N, S, R)$ is a *context-sensitive* grammar if for all productions $\alpha \rightarrow \beta \in R$, $|\alpha| \leq |\beta|$, that is, the right-hand side of each production is not shorter than its left-hand side. G is a *context-free* grammar if $|\alpha| = 1$, that is, the left-hand side of each production consists of a single non terminal. G is a *left-linear* grammar if G is context-free and β (the right-hand side of the production) is either of the form Aw or of the form w where $A \in N$ and $w \in T^*$; in a *right-linear* grammar β always is of the form wA or w. A right or left-linear grammar is called a *regular* grammar. G_1, in Example 1, is context sensitive and context free.

It is straightforward to show that the classes of languages generated by these classes of grammars stand in strict equality or subset relationships. Specifically, the class of languages generated by right-linear grammars is the same as the class generated by left-linear grammars; this class is called the *regular* languages, and is a strict subset of the class of languages generated by context-free grammars, which is a strict subset of the class of languages generated by context-sensitive grammars, which in turn is a strict subset of the class of languages generated by rewrite grammars.

It turns out that context-sensitive grammars (where a production rewrites more than one nonterminal) have not had many applications in natural language processing, so from here on we will concentrate on context-free grammars, where all productions take the form $A \rightarrow \beta$, where $A \in N$ and $\beta \in (N \cup T)^+$.

An appealing property of grammars with productions in this form is that they induce tree structures on the strings that they generate. And, as Section Probability and Statistics shows, this is the basis for bringing in probability distributions and the theory of inference. We say that the context-free grammar $G = (T, N, S, R)$ generates the labeled, ordered tree ψ, iff the root node of ψ is labeled S, and for each node n in ψ, either n has no children and its label is a member of T (i.e., it is labelled with a terminal) or else there is a production $A \rightarrow \beta \in R$ where the label of n is A and the left-to-right sequence of labels of n's immediate children is β. It is straightforward to show that w is in L_G if G generates a tree ψ whose *yield* (i.e., the left-to-right sequence of terminal symbols labeling ψ's leaf nodes) is w; ψ is called a *parse tree* of w (with respect to G). In what follows, we define Ψ_G to be the set of parse trees generated by G, and $\mathscr{Y}^G(\cdot)$ to be the function that maps trees to their yields.

Example 1 (continued): The grammar G_1 defined above generates the following two trees, ψ_1 and ψ_2.

In this example, $\mathscr{Y}(\psi_1) =$ 'rice grows' and $\mathscr{Y}(\psi_2) =$ 'wheat grows.'

A string of terminals w is called *ambiguous* if w has two or more parse trees. Linguistically, each parse tree of an ambiguous string usually corresponds to a distinct interpretation.

Example 2: Consider $G_2 = (T_2, N_2, S, R_2)$, where $T_2 = \{$I, saw, the, man, with, telescope$\}$, $N_2 = \{$S, NP, N, Det, VP, V, PP, P$\}$ and $R_2 = \{$S $\rightarrow$ NP, VP, NP $\rightarrow$ I, NP $\rightarrow$ Det N, Det $\rightarrow$ the, N $\rightarrow$ NP, PP, N $\rightarrow$ man, N $\rightarrow$ telescope, VP $\rightarrow$ V, NP, VP $\rightarrow$ VP, PP, PP $\rightarrow$ P, NP, V $\rightarrow$ saw, P $\rightarrow$ with$\}$. Informally, N rewrites to nouns, Det to determiners, V to verbs, P to prepositions and PP to prepositional phrases. It is easy to check that the two trees ψ_3 and ψ_4 with the yields $\mathscr{Y}(\psi_3) = \mathscr{Y}(\psi_4) =$ 'I saw the man with the telescope' are both generated by G_2. Linguistically, these two parse trees represent two different syntactic analyses of the sentence. The first analysis corresponds to the interpretation where the seeing is by means of a telescope, while the second corresponds to the interpretation where the man has a telescope.

Probability and Statistics

Obviously broad coverage is desirable – natural language is rich and diverse, and not easily held to a small set of rules. But it is hard to achieve broad coverage without massive ambiguity (a sentence may have tens of thousands of parses), and this of course complicates applications like language interpretation, language translation, and speech recognition. This is the dilemma of coverage that we referred to earlier, and it sets up a compelling role for probabilistic and statistical methods.

We briefly review the main probabilistic grammars and their associated theories of inference. We begin in Section Regular Grammars with probabilistic regular grammars, also known as hidden Markov models (HMM), which are the foundation of modern speech recognition systems—see Jelinek (1997) for a survey.

In Section Context-Free Grammars we discuss probabilistic context-free grammars, which turn out to be essentially the same thing as branching processes. Finally, in Section Gibbs Distributions, we take a more general approach to placing probabilities on grammars, which leads to Gibbs distributions, a role for Besag's pseudolikelihood method (Besag 1974, 1975), various computational issues, and, all in all, an active area of research in computational linguistics.

Regular Grammars

We will focus on right-linear grammars, but the treatment of left-linear grammars is more or less identical. It is convenient to work with a *normal form*: all rules are either of the form $A \rightarrow bB$ or $A \rightarrow b$, where $A, B \in N$ and $b \in T$. It is easy to show that every right-linear grammar has an equivalent normal form in the sense that the two grammars produce the same language. Essentially nothing is lost.

Probabilities

The grammar G can be made into a probabilistic grammar by assigning to each nonterminal $A \in N$ a probability distribution p over productions of the form $A \rightarrow \alpha \in R$: for every $A \in N$

$$\sum_{\substack{\alpha \in (N \cup T)+ \\ \text{s.t. } (A \rightarrow \alpha) \in R}} p(A \rightarrow \alpha) = 1 \qquad [1]$$

Recall that Ψ_G is the set of parse trees generated by G (see Section Grammars and Languages). If G is linear, then $\psi \in \Psi_G$ is characterized by a sequence of productions, starting from S. It is, then, straightforward to use p to define a probability P on Ψ_G: just take $P(\psi)$ (for $\psi \in \Psi_G$) to be the product of the associated production probabilities.

S $\rightarrow$ aS	$p = 0.80$
S $\rightarrow$ bS	$p = 0.01$
S $\rightarrow$ bA	$p = 0.19$
A $\rightarrow$ bA	$p = 0.90$
A $\rightarrow$ b	$p = 0.10$

Example 3: Consider the right-linear grammar $G_3 = (T_3, N_3, S, R_3)$, with $T_3 = \{a, b\}$, $N_3 = \{S, A\}$ and the productions (R_3) and production probabilities (p):

The language is the set of strings ending with a sequence of at least two *b*s. The grammar is ambiguous: in general, a sequence of terminal states does not uniquely identify a sequence of productions. The sentence *aabbbb* has three parses (determined by the placement of the production S → bA), but the most likely parse, by far, is S → aS, S → aS, S → bA, A → bA, A → bA, A → b ($P = 0.8 \cdot 0.8 \cdot 0.19 \cdot 0.9 \cdot 0.1$), which has a *posterior* probability of nearly 0.99. The corresponding parse tree is shown below.

Inference

The problem is to estimate (see Estimation: Point and Interval) the transition probabilities, $p(\cdot)$, either from parsed data (examples from Ψ_G) or just from sentences (examples from L_G). Consider first the case of parsed data ('supervised learning'), and let $\psi_1, \psi_2, \ldots, \psi_n \in \Psi$ be a sequence taken iid according to P. If $f(A \to \alpha; \psi)$ is the counting function, counting the number of times transition $A \to \alpha \in R$ occurs in ψ, then the likelihood function (see Likelihood in Statistics) is

$$L = L(p; \psi_1, \ldots, \psi_n) = \prod_{i=1}^{n} \prod_{A \to \alpha \in R} p(A \to \alpha)^{f(A \to \alpha; \psi_i)} \qquad [2]$$

The maximum likelihood estimate is, sensibly, the relative frequency estimator:

$$\widehat{p}(A \to \alpha) = \frac{\sum_{i=1}^{n} f(A \to \alpha; \psi_i)}{\sum_{i=1}^{n} \sum_{\beta s.t} {}_{A \to \beta \in R} f(A \to \beta; \psi_i)} \qquad [3]$$

The problem of estimating p from sentences ('unsupervised learning') is more interesting, and more important for applications. Recall that $\mathscr{Y}(\psi)$ is the yield of ψ, that is the sequence of terminals in ψ. Given a sentence $w \in T^+$, let Ψ_w be the set of parses which yield $w : \Psi_w = \{\psi \in \Psi : \mathscr{Y}(\psi) = w\}$. Imagine a sequence $\psi_1, \ldots, \psi_n$, iid according to P, for which only the corresponding yields, $w_i = \mathscr{Y}(\psi_i) \quad 1 \le i \le n$, are observed. The likelihood function is

$$L = L(p; w_1, \ldots, w_n) = \prod_{i=1}^{n} \sum_{\psi \in \Psi_{w_i}} \prod_{A \to \alpha \in R} p(A \to \alpha)^{f(A \to \alpha; \psi_i)} \qquad [4]$$

As is usual with hidden data, there is an EM-type iteration for climbing the likelihood surface – see Baum (1972) and Dempster et al. (1977):

$$t + 1(A \to \alpha) = \frac{\sum_{i=1}^{n} E_{\hat{p}_i}[f(A \to \alpha; \psi) \psi \in \Psi_{w_i}]}{\sum_{A \to \beta \in R} \sum_{i=1}^{n} E_{\hat{p}_i}[f(A \to \beta; \psi) \psi \in \Psi_{w_i}]} \qquad [5]$$

Needless to say, nothing can be done with this unless we can actually evaluate, in a computationally feasible way, expressions like $E_{\hat{p}}[f(A \to \alpha; \ \psi) | \psi \in \Psi_w]$. This is one of several closely related computational problems that are part of the mechanics of working with regular grammars.

Computation

A sentence $w \in T^+$ is *parsed* by finding a sequence of productions $A \to bB \in R$ which yield w. Depending on the grammar, this corresponds more or less to an interpretation of w. Often, there are many parses and we say that w is ambiguous. In such cases, if there is a probability p on R then there is a probability P on Ψ, and a reasonably compelling choice of parse is the most likely parse:

$$\arg\max_{\psi \in \Psi_w} P(\psi) \qquad [6]$$

This is the *maximum a posteriori* (MAP) estimate of ψ—obviously it minimizes the probability of error under the distribution P. (Of course, in those cases in which Eqn. [6] is small, P does little to make w unambiguous.)

What is the probability of w? How are its parses computed? How is the most likely parse computed? These computational issues turn out to be more-or-less the same as the issue of computing $E_{\hat{p}}[f(A \to \alpha; \psi) | \psi \in \Psi_w]$ that came up in our discussion of inference. The basic structure and cost of the computational algorithm is the same for each of the four problems – compute the probability of w, compute the set of parses, compute the best parse, compute $E_{\hat{p}}$. In particular, there is a simple dynamic programming solution to each of these problems, and in each case the complexity is of the order $n \cdot |R|$, where n is the length of w, and $|R|$ is the number of productions in G – see Jelinek (1997), Geman and Johnson (2000). The existence of a dynamic programming principle for regular grammars is a primary reason for their central role in state-of-the-art speech recognition systems.

Context-Free Grammars

Despite the successes of regular grammars in speech recognition, the problems of language understanding and translation are generally better addressed with the more structured and more powerful context-free grammars. Following our development of probabilistic regular grammars in the previous section, we will address here the interrelated issues of fitting context-free grammars with probability distributions,

estimating the parameters of these distributions, and computing various functionals of these distributions.

The context-free grammars $G = (T, N, S, R)$ have rules of the form $A \to \alpha$, $\alpha \in (N \cup T)^+$, as discussed previously in Section Grammars and Languages. There is again a normal form, known as the Chomsky normal form, which is particularly convenient when developing probabilistic versions. Specifically, one can always find a context-free grammar G', with all productions of the form $A \to BC$ or $A \to a$, $A, B, C \in N$, $\alpha \in T$, which produces the same language as G: $L_{G'} = L_G$. Henceforth, we will assume that context-free grammars are in the Chomsky normal form.

Probabilities

The goal is to put a probability distribution on the set of parse trees generated by a context-free grammar in Chomsky normal form. Ideally, the distribution will have a convenient parametric form, that allows for efficient inference and computation.

Recall from Section Grammars and Languages that context-free grammars generate labeled, ordered trees. Given sets of nonterminals N and terminals T, let Ψ be the set of finite trees with:

a. root node labeled S;
b. leaf nodes labeled with elements of T;
c. interior nodes labeled with elements of N;
d. every nonterminal (interior) node having either two children labeled with nonterminals or one child labeled with a terminal.

Every $\psi \in \Psi$ defines a sentence $w \in T^+$: read the labels off of the terminal nodes of ψ from left to right. Consistent with the notation of Section Regular Grammars we write $\mathscr{Y}(\psi) = w$. Conversely, every sentence $w \in T^+$ defines a subset of Ψ, which we denote by Ψ_w, consisting of all ψ with yield $w(\mathscr{Y}(\psi) = w)$. A context-free grammar G defines a subset of Ψ, Ψ_G, whose collection of yields is the language, L_G, of G. We seek a probability distribution P on Ψ which concentrates on Ψ_G.

The time-honored approach to probabilistic context-free grammars is through the production probabilities $p : R \to [0, 1]$, with

$$\sum_{\substack{\alpha \in N^2 \cup T \\ \text{s.t.}(A \to \alpha) \in R}} p(A \to \alpha) = 1 \qquad [7]$$

Following the development in Section Regular Grammars, we introduce a counting function $f(A \to \alpha; \psi)$, which counts the number of instances of the rule $A \to a$ in the tree ψ, i.e., the number of nonterminal nodes A whose daughter nodes define, left-to-right, the string α. Through f, p induces a probability P on Ψ:

$$P(\psi) = \prod_{(A \to \alpha) \in R} P(A \to \alpha)^{f(A \to \alpha; \psi)} \qquad [8]$$

It is clear enough that P concentrates on Ψ_G, and we shall see shortly that this parameterization, in terms of products of probabilities p, is particularly workable and convenient. The pair, G and P, is known as a probabilistic context-free grammar, or PCFG for short. (Notice the connection to branching processes – Harris (1963): Starting at S, use R, and the associated probabilities $p(\cdot)$, to expand nodes into daughter nodes until all leaf nodes are labeled with terminals – i.e., with elements of T.)

Inference

As with probabilistic regular grammars, the production probabilities of a context-free grammar, which amount to a parameterization of the distribution P on Ψ_G, can be estimated from examples. In one scenario, we have access to a sequence $\psi_1, \ldots, \psi_n$ from Ψ_G under P. This is 'supervised learning,' in the sense that sentences come equipped with parses. More practical is the problem of 'unsupervised learning,' wherein we observe only the yields, $\mathscr{Y}(\psi_1), \ldots \mathscr{Y}(\psi_n)$.

In either case, the treatment of maximum likelihood estimation is essentially identical to the treatment for regular grammars. In particular, the likelihood for fully observed data is again Eqn. [2], and the maximum likelihood estimator is again the relative frequency estimator Eqn. [3]. And, in the unsupervised case, the likelihood is again Eqn. [4] and this leads to the same EM-type iteration given in Eqn. [5].

Computation

There are again four basic computations: find the probability of a sentence $w \in T^+$, find a $\psi \in \Psi$ (or find *all* $\psi \in \Psi$) satisfying $\mathscr{Y}(\psi) = w$ ('parsing'); find

$$\arg\max_{\substack{\psi \in \Psi_{\text{s.t.}} \\ \mathscr{Y}(\psi) = w}} P(\psi)$$

('maximum *a posteriori*' or 'optimal' parsing); compute expectations of the form $E_{\hat{p}_t}[f(A \to \alpha; \psi) | \psi \in \Psi_w]$ that arise in iterative estimation schemes like (5). The four computations turn out to be more-or-less the same, as was the case for regular grammars (Section Computation) and there is again a common dynamic-programming-like solution – see Lari and Young (1990, 1991), Geman and Johnson (2000).

Gibbs Distributions

There are many ways to generalize. The coverage of a context-free grammar may be inadequate, and we may hope, therefore, to find a workable scheme for placing probabilities on context-sensitive grammars, or perhaps even more general grammars. Or, it may be preferable to maintain the structure of a context-free grammar, especially because of its dynamic programming principle, and instead generalize the class of probability distributions away from those induced (parameterized) by production probabilities. But nothing comes for free. Most efforts to generalize run into nearly intractable computational problems when it comes time to parse or to estimate parameters.

Many computational linguists have experimented with using Gibbs distributions, popular in statistical physics, to go beyond production-based probabilities, while nevertheless preserving the basic context-free structure. Next we take a brief look at this particular formulation, in order to illustrate the various challenges that accompany efforts to generalize the more standard probabilistic grammars.

Probabilities

The sample space is Ψ_G, the set of trees generated by a context-free grammar G. Gibbs measures are built from sums of more-or-less simple functions, known as 'potentials' in statistical physics, defined on the sample space. In linguistics, it is more natural to call these features rather than potentials. Suppose, then, that we have identified M linguistically salient features $f_1, \ldots, f_M$, where f_k: $\Psi_G \to R$, through which we will characterize the fitness or appropriateness of a structure $\psi \in \Psi_G$. More specifically, we will construct a class of probabilities on Ψ_G which depend on $\psi \in \Psi_G$ only through $f_1(\psi), \ldots, f_M(\psi)$. Examples of features are the number of times a particular production occurs, the number of words in the yield, various measures of subject-verb agreement, and the number of embedded or independent clauses.

Gibbs distributions have the form

$$P_\theta(\psi) = \frac{1}{Z}\exp\left\{\sum_{i=1}^{M}\theta_i f_i(\psi)\right\} \qquad [9]$$

where $\theta_1, \ldots, \theta_M$ are parameters, to be adjusted 'by hand' or inferred from data, $\theta = (\theta_1, \ldots, \theta_M)$, and where $Z = Z(\theta)$ (known as the 'partition function') normalizes so that $P_\theta(\Psi) = 1$. Evidently, we need to assume or ensure that $\sum_{\psi\in\Psi_G}\exp\{\sum_1^M\theta_i f_i(\psi)\} < \infty$. For instance, we had better require that $\theta_1 < 0$ if $M = 1$ and $f_1(\psi) = |\mathscr{Y}(\psi)|$ (the number of words in a sentence), unless of course $|\Psi_G| < \infty$.

Relation to Probabilistic Context-Free Grammars

Gibbs distributions are much more general than probabilistic context-free grammars. In order to recover PCFG's, consider the special feature set $\{f(A \to \alpha; \psi)\}_{A\to\alpha\in R}$: The Gibbs distribution Eqn. [9] takes on the form

$$P_\theta(\psi) = \frac{1}{Z}\exp\left\{\sum_{A\to\alpha\in R}\theta_{A\to\alpha}\mathrm{f}(A\to\alpha;\psi)\right\} \qquad [10]$$

Evidently, then, we get the probabilistic context-free grammars by taking $\theta_{A\to\alpha} = \log_e p(A \to \alpha)$, where p is a system of production probabilities consistent with Eqn. [7], in which case $Z = 1$. But is Eqn. [10] more general? Are there probabilities on Ψ_G of this form that are not PCFGs? The answer turns out to be no, as was shown by Chi (1999) and Abney et al. (1999): given a probability distribution P on Ψ_G of the form of Eqn. [10], there always exists a system of production probabilities p under which P is a PCFG.

Inference

The feature set $\{f_i\}_{i=1,\ldots,M}$ can be accommodate arbitrary linguistic attributes and constraints, and the Gibbs model Eqn. [9], therefore, has great promise as an accurate measure of linguistic fitness. But the model depends critically on the parameters $\{\theta_i\}_{i=1,\ldots,M}$, and the associated estimation problem is, unfortunately, very hard. Indeed, the problem of unsupervised learning appears to be all but intractable.

Let us suppose, then, that we observe $\psi_1, \psi_2, \ldots, \psi_n \in \Psi_G$ ('supervised learning'), iid according to P_θ. In general, the likelihood function, $\prod_{i=1}^n P_\theta(\psi_i)$, is more or less impossible to maximize. But if the primary goal is to select good parses, then perhaps the likelihood function asks for too much, or even the wrong thing. It might be more relevant to maximize the likelihood of the observed parses, *given the yields* $\mathscr{Y}(\psi_1), \ldots, \mathscr{Y}(\psi_n)$:

$$\prod_{i=1}^{n} P_\theta(\psi_i|\mathscr{Y}(\psi_i)) \qquad [11]$$

Maximization of Eqn. [11] is an instance of Besag's remarkably effective pseudolikelihood method (Besag 1974, 1975), which is commonly used for estimating parameters of Gibbs's distributions. The computations involved are generally much easier than what is involved in maximizing the ordinary likelihood function. Take a look at the gradient of the logarithm of Eqn. [11]: the θ_j component is proportional to

$$\frac{1}{n}\sum_{i=1}^{n} f_j(\psi_i) - \frac{1}{n}\sum_{i=1}^{n} E_0\left[f_j(\psi)|\mathscr{Y}(\psi) = \mathscr{Y}(\psi_i)\right] \qquad [12]$$

and $\mathrm{E}_\theta[f_j(\psi)|\mathscr{Y}(\psi)]$ can be computed directly from the set of parses of the sentence $\mathscr{Y}(\psi)$. (In practice there is often massive ambiguity, and the number of parses may be too large to feasibly consider. Such cases require some form of pruning or approximation.)

Thus gradient ascent of the pseudolikelihood function is (at least approximately) computationally feasible. This is particularly useful since the Hessian of the logarithm of the pseudolikelihood function is non-positive, and therefore there are no local maxima. What is more, under mild conditions pseudolikelihood estimators (i.e., maximizers of Eqn. [11]) are consistent; (Chi 1998).

Abstract

While games of chance have been played for thousands of years, and while experienced players often had good intuitive ideas of the relative frequencies of various outcomes, the concept of probability as referring to the ratio of favorable outcomes to total outcomes of a 'fair' gambling device emerged only 500 or so years ago in Western societies. That allowed evaluation of new games not yet played and later led to a more abstract conception of probability as a measure satisfying certain conditions ('axioms'). Only in the past 150 years or so has probability had a major role in science and only in the last 50 years or so in everyday life – as, for example, in evaluating medical outcomes or technological risks or manufacturer liability. Thus, especially in attempting to assess probability in everyday situations, our intuitions are often deficient – more so than those concerning quantity, space, and time. The major problem is not, however, one of making random errors in probability judgments but of making systematic ones that result from a number of well-known and research systematic cognitive biases and heuristics, which are described in this article. These systematic departures from rational assessment do not imply that coherent and accurate probabilistic thinking is (anywhere near) impossible, but that when departures from coherence and accuracy occur, they tend to follow a predictable pattern.

Introduction

Some people have enjoyed playing games that involved at least a component of chance ever since civilizations – as we know them – emerged in human history. Many of these people apparently had a fairly good intuitive idea of what we might now term the 'probabilities' or 'odds' of various outcomes associated with these games. Alternatively, at least some people (whom in hindsight we might now label 'superstitious') believed that the outcomes of these games could indicate something about the favorability of the world in general toward the gambler (a belief that may exist even today – at least on an implicit basis – for chronic gamblers), specifically the favorability or unfavorability of a particular god that was involved with a particular game.

In the last 600 years or so, people have proposed systematic ways of evaluating probabilities – e.g., in terms of equally likely outcomes in games of chance or in terms of subjective belief. In the last 150 years or so, scientific endeavor has started to make specific use of probabilistic thinking, and in the last 100 years or so, probabilistic ideas have been applied to problems of everyday life (see Gigerenzer et al., 1989). Currently, for example, jurors are often asked to determine manufacturer or company liability on the basis of differential rates of accidents or cancers; in such judgments, jurors cannot rely on deterministic reasoning that would lead to a specification of exactly which negative outcome is due to what nor can they rely on 'experience' in these contexts in which they have had none. Thus, it is extraordinarily important to understand – if, indeed, generalizations about such thinking are possible – how it is that people think about and evaluate probabilities, and, in particular, the problems that they (we) have. The major thesis presented here is that both the thinking and the problems can be understood in terms of *systematic deviations* from the normative principles of probabilistic reasoning that have been devised over the past five or so centuries. These deviations are not inevitable; it is certainly possible for people to think about probabilities coherently (at least on occasion); nevertheless, *when* deviations occur, they tend to be of the systematic nature to be described here; they occur most often when people are engaged in what is termed 'automatic' or 'associational' thinking, as opposed to 'reflective' and 'comparative' thinking. (These terms will be made more precise later in this article.)

A Brief History (of Thought)

Beginning in early infancy, we develop intuitions about space, time, and number (at least to the extent of 'one, two, three, many'). These intuitions are essentially correct. They remain throughout our lives basically unaltered except for small variations, and they form the foundation of far more sophisticated mathematical systems that have been developed over the past thousands of years. Moreover, their importance in our lives has been clear throughout those millennia.

In contrast, probabilistic thinking is often unintuitive, and it generally can be taught only after we are familiar with fractions, so that analogs to relative frequency are clear. Moreover, our intuitions about probabilities are often just plain wrong. For example, belief in the 'gambler's fallacy' (negative recency) can even be explicitly rejected, but nevertheless implicitly influence decision making – such as when people demand a greater amount of money in preference to gambling on an outcome that is 'due' (e.g., a tail after five straight heads) than in preference to gambling on one that is not (e.g., an additional head); see Gold (1997).

The fairly recent, and somewhat 'iffy,' use of probabilistic judgment does not imply, however, that people did not gamble throughout the centuries. As mentioned previously, the outcomes of games of chance could provide not just monetary winners and losers but 'signals' from 'the gods' about

[†] Deceased.

favorability toward the gambler; this belief is well captured by the narrative of the novelist Robert Graves (1943) about Caligula's gambling shortly before his assassination. This tyrant is both watching gladiator games, often putting to death people he has bribed to lose, and rolling a form of dice called 'astragali' – which are four-sided dice made from pig or lamb bones.

Caligula is playing with his Uncle Claudius, who in order to avoid winning (a dangerous outcome for Claudius) hands the emperor beautiful new dice loaded to come up with a 'Venus roll,' which consists of four separate sides (generally with the numbers 1, 3, 4, and 6). Caligula's subsequent success convinces him that Venus is favorable toward him that day, and he does not take the usual precautions upon leaving the games. Throughout his life, Claudius feels guilty that the loaded dice sent the wrong message to Caligula about how Venus felt about him that day – an inappropriate intervention between a god and a man. (According to Hacking, 1975, the interpretation of such events as 'signals' from 'on high' is common up to the Renaissance, even after people in Europe had given up polytheism for monotheism; the reader might also note how often in the *Old Testament* people decide to 'cast lots' to decide what to do – apparently in the belief that God would determine the outcome.)

Of course, not everyone believed in such intervention. For example, Cicero is quoted as claming that "Nothing is so unpredictable as a throw of the dice [modern translation]," and that "both now and then indeed he will make it [the Venus roll] twice and even thrice in succession. Are we going to be so feebleminded then as to aver that such a thing happened by the personal intervention of Venus rather than by pure luck?" (see David, 1962: p. 25).

Among those not so superstitious (such as Cicero, who was himself assassinated), the intuitive understanding gained through experience of which bets are good ones and which bets are bad ones led to fairly good implicit estimates of probability. Even now, however, Wagenaar (1988) finds chronic gamblers to be more reliant on intuition and experience than on mathematical analysis.

In contrast, explicit probabilistic thinking goes beyond experience. We can, for example, indicate what are good or bad bets in gambles we have just now constructed, with which we have had no previous experience. Probabilistic thinking can also be extended to 'personal belief' about uncertain events, it can be used to evaluate risks, and it can serve as a guide for social policy.

Systematic, probabilistic thinking appears to have started with questions about gambling (in particular about gambles that have not yet been played multiple times). Despite the fact that people gambled a lot, however, the formal theory did not begin until the Italian Renaissance, specifically in correspondence and argumentation between Geronimo Cardano (1501–76) and his associates. The approach that has been ascribed to Cardano involved *comparative* rather than associational thinking. He proposed that the likelihood of success of a gamble could be *computed*, or at least approximated, by comparing the number of outcomes of the device favorable to the gambler divided by the total number of outcomes. In situations where the gambling device is set up to make each possible outcome equally likely, this ratio assessment of probability is used today. The ratio assessment leads to certain general principles, often termed 'axioms,' which, in turn, provide a more abstract notion of probability, and allow different interpretations of probability to be developed – just provided they lead to measures consistent with the axioms. For example, Ramsey (1931) demonstrated that when explicit probabilities are used to determine fair gambling odds, then the gambler will follow the basic principles of probability theory if and only if it is not possible to make a 'Dutch Book' (see de Finetti, 1974–75: p. 87) such that the gambler always loses; that is, the gambler will be consistent if and only if it is impossible for a highly intelligent opponent to make a series of bets such that the opponent always wins.

After Cardano, the idea of probabilistic inference developed quite rapidly. Many French and Dutch intellectuals corresponded with each other about what constituted better or worse bets – not just in games that had been played chronically, but in games of their own invention. Interestingly, when they discussed probability, they often did so in terms of the expected value of the game, and questions were often posed as to which of the two games had a higher expected value. Then there was rapid development of probability theory – for example, Bernoulli's 'Law of Large Numbers,' which specified the relationship between the probability of a single outcome and the probability distribution of multiple outcomes of the same type (for example, the relationship between the probability a fair coin comes up heads and the probability that it comes up heads at least three times in 10 trials); the 'law' itself derived the limit of the proportion of heads as the number of trials becomes indefinitely large. To jump ahead to recent times, von Neumann and Morgenstern published their classic work *Theory of Games and Economic Behavior* (1944/1947), in which again the question was one of choosing between different gambles, but in terms of expected utility rather than expected value. This work was quite consistent with the earliest work, in which the question of probability was secondary to the question of choice between alternative courses of action.

Probability Assessments

All probabilistic analysis is based on the idea that (suitably trained and intelligent) people can at least *recognize* good probabilistic arguments presented by someone else, or discovered or thought of by themselves, but not necessarily generate good assessments. The very fact that there was correspondence about the gambles – and occasionally some disputes about them – indicated that people do not automatically assess probabilities in the same way, or accurately (e.g., corresponding to relative frequencies, or making good gambling choices).

The von Neumann and Morgenstern work, however, does involve some *psychological* assumptions that people can engage in 'good' probabilistic thinking. First, they must do so implicitly, so that the choice follows certain 'choice axioms' that allow the construction of an expected utility model – i.e., a model that *represents* choice as a maximization of implicit expected utility, that, in turn, requires that probabilities at the very least follow the standard axioms of probability theory. It also implies considering conditional probabilities in a rational

manner, which is done only when implicit or explicit conditional probabilities are consistent with Bayes' theorem. Thus, the von Neumann and Morgenstern work required that people be 'Bayesian' in a consistency sense, although that term is sometimes used to imply that probabilities should at base be interpreted as degrees of belief. Another way in which probability assessment must be 'good' is that there should be some at least reasonable approximation between probabilities and long-term relative frequencies; in fact, under particular circumstances (of interchangeability and indefinitely repeated observations), the probabilities of someone whose belief is constrained by Bayes' theorem must approximate relative frequencies (Dawid, 1982).

Are people always coherent? Consider an analogy with swimming. People do swim well, but occasionally we drown. What happens is that there is particular systematic bias in attempting to swim that makes it difficult. We want to hold our heads above water. When, however, we raise our heads to do so, we tend to assume a vertical position in the water, which is one of the few ways of drowning (aside from freezing or exhaustion or being swept away in rough waters).

Just as people drown occasionally by trying to hold their heads above water, people systematically deviate from the rules of probabilistic thinking. Again, however, the emphasis is on 'systematic.' For example, there is now evidence that people's probabilistic judgments are 'subadditive' – in that when a general class is broken into components, the judgmentally estimated probabilities assigned to disjoint components that comprise the class sum to a larger number than the probability assigned to the class. That is particularly true in memory, where, for example, people may recall the frequency with which they were angry at a close friend or relative in the last month and the frequency with which they were angry at a total stranger, and the sum of the estimates is greater than an independent estimate of being angry period (even though it is possible to be angry at someone who is neither a close friend or relative nor a total stranger; see Mulford and Dawes, 1999). The clever opponent will then bet against the occurrence of each component but on the occurrence of the basic event, thereby creating a Dutch Book.

The Heuristics and Biases Approach to Problems of Probabilistic Thinking

The basic conception is that we all use a series of 'heuristics' in our everyday estimation (explicit or implicit) of probabilities, and these heuristics lead to biases. These heuristics provide a type of 'bounded rationality' (Simon 1955, 1956, 1979) – in that they substitute for a very detailed or logical analysis, an analysis that may be beyond our 'computational capacity.' Just as associational thinking serves us well in many contexts, however, so do the heuristics. Occasionally, however, they lead to grossly erroneous – systematically erroneous – probabilistic thinking. The conception that heuristics have some type of 'generalized validity,' but that they often lead us astray, was well argued in a classic *Science* article by Tversky and Kahneman (1974); unfortunately, the principle has been lost on some critics, who can point out many situations in which these heuristics 'work.' Naturally, they do. If they did not have some sort of generalized utility, they would not have survived over generations of people trying to make probabilistic judgments.

One of the most important of these heuristics is termed the 'representativeness' heuristic, which was first proposed by Tversky and Kahneman in an article concerning *Belief in the Law of Small Numbers* (1971). The idea supported in that article is that we expect very small samples to 'represent' the populations from which they were drawn, where the 'we' includes even people with a fair amount of formal training in statistics. That expectation leads to judgment of probability on the basis of the degree to which an instance or a sample *matches* a population or general idea, rather than on a judgment of how it can be generated. For example, when tossing a coin, a result consisting of six heads appears to be much less likely than one of a head followed by two tails, followed by two heads, and finally a tail. But, of course, each of the sequences is equally likely; each occurs with probability 1/64. In fact, the sequence of a head followed by two tails followed by two heads and a tail is seen as more likely than a sequence of strict alternation of heads and tails – even though, in general, people believe that there is more than a chance amount of alternation when they judge what is truly 'random' (and in fact are most apt to pick as random the sequence that has a transition probability of 2/3 rather than 1/2). This incorrect expectation of alternation leads to such erroneous beliefs as that in the 'hot hand' in basketball when observing clusters of similar outcomes (e.g., successful shots). See, for example, Gilovich et al. (1985).

Another heuristic is termed as availability one. Briefly, we estimate frequencies on the ease with which instances 'come to mind,' or on our judgment of the ease with which we can recall or generate instances. It is, in fact, generally true that when there are more instances as opposed to fewer in the world, we find it easier to recall or generate more as opposed to fewer. The problem is, however, that there are determinants of ease of recall or generation that are independent of – or sometimes even in conflict with – actual relative frequency in our environment. For example, vivid instances are more readily recalled than pallid ones. (See again the result on 'subadditivity' in memory.) Moreover, instances that are easily imaginable (even if we have not actually experienced them) are more readily 'brought to mind' than are those difficult to imagine.

The availability heuristic creates a bias when we are unaware of the factors other than frequency that can result in ease of recall or generation, but use it as a way of estimating actual frequency. Sometimes, the bias is so strong that we even ignore instances that we *cannot* sample – a 'structural availability' problem. For example, clinical psychologists often claim that no child sexual abusers stop on their own without therapy. When asked to substantiate this claim, they will cite many of the child abusers with whom they have had contact, often mandated by a judge to enter therapy with them. The problem is, however, that they would not have had contact with any who had stopped on their own, and by definition they were seeing people only in a therapy setting, hence could not observe any of them stopping 'without therapy.' Nevertheless, the experience with such people is so salient and compelling that even while acknowledging the logical problem with the conclusion, many of these clinical psychologists simply revert to the belief a day

or a week after having publicly recognized the availability bias (see Dawes, 1988: p. 102).

Following the ideas of Fischhoff and Beyth-Marom (1983) as elaborated by Dawes (1998), the standard cognitive biases and heuristics can be understood by alluding to simple forms of Bayes' theorem. Consider, for example, the relationship between a symptom S and a disease D, and suppose a diagnostician observes this symptom S. If the probability of the disease is assessed on the basis of a pure matching or association between the symptom and the disease, independent of considerations of conditional probability, there is no normative structure to which the judgment corresponds. More often, however, the judgment will be made on the basis of the conditional probabilities – a normatively correct judgment if it is based on the conditional probability of the disease given the symptom, $P(D/S)$, but a representative judgment if it is the probability of the symptom given the disease, $P(S/D)$. Unfortunately, there is a lot of evidence that the judgment is often made on the basis of the latter relationship – when conditional probabilities are considered at all.

The relationship between these two probabilities is given by rewriting Bayes' theorem as:

$$P(D/S) = \frac{P(S/D)P(D)}{P(S)} \qquad [1]$$

It can also be written in terms of the 'ratio rule':

$$\frac{P(D/S)}{P(S/D)} = \frac{P(D)}{P(S)} \qquad [2]$$

Because the ratio rule follows from the very definition of conditional probability, it is simply incoherent to equate the probability of the disease given the symptom with the probability of the symptom given the disease in the absence of a simultaneous belief that the probability of the disease and the probability of the symptom are identical. (Again, if someone were to make a series of bets based on 'fair betting odds' in such a belief, an opponent could make a Dutch Book against that person.) Classic representative thinking – e.g., 'she gave a typical schizophrenic response, therefore she must be schizophrenic' – embraces such an identity. What is critical, of course, are the *base rates* of D and S, yet extensive research has shown that people underutilize such base rates in their intuitive judgments – or at least fail to incorporate them to a sufficient extent into their prior beliefs, given that they are often seen as 'not relevant.' (Why, people often ask, should the *general* probabilities of these symptoms and diseases be relevant to a particular judgment about a particular person with a particular symptom? Such an argument is sometimes even followed by bland assertions to the effect that 'statistics do not apply to the individual' – a wholly erroneous conclusion, as can be attested to by the heavy cigarette smoker who develops lung cancer.)

People often do not ignore these base rates *entirely* in the judgments, particularly if the probabilistic nature of the judgment is made clear (see Gigerenzer et al., 1989). Nevertheless, the 'underutilization' of such base rates is ubiquitous. In the psychological literature it was first decried by Meehl and Rosen (1955), who noted that in case conferences they attended, clinical psychology and psychiatry judges tended to ignore base rates completely; later, underutilization has been established in a variety of experimental situations using a wide variety of subjects, especially by Kahneman and Tversky (1972, 1973). For example, when asked to judge whether a description is of a particular engineer or a particular lawyer, subjects make the same judgment whether the experimenter states that the description was drawn from a pool of 70% engineers and 30% lawyers, or vice versa. As Bar-Hillel (1990) points out, the 70/30 split does not appear to be 'relevant,' but it's relevance would most likely be clear if the split were 99/1, and certainly if it were a 100/0. (Again, we can hypothesize that people can recognize probabilistic arguments – although it's possible to be fooled on occasion – but often not make them spontaneously.) Thus, for example, someone who is said to be interested in sailing and carpentry and sharing model train sets with a child is judged to be much more likely to be an engineer than a lawyer, whether this person was drawn from a pool of 70% engineers or 70% lawyers. Making the sampling procedure absolutely 'transparent' does, however, reduce that tendency.

The use of Bayes' theorem to understand the relationship between symptoms and disease leads naturally to its use to consider the general relationship between any hypotheses and any bit of evidence. Let e refer to some bit of evidence about whether a hypothesis h is or is not true; for example, a symptom may be regarded as a bit of evidence, and having a particular disease a hypothesis; or the hypothesis may concern who is going to win the election in the United States in the year 2020 and a particular bit of evidence may be the margin of victory or defeat of the potential candidate in a more local election. Bayes' theorem expressed in terms of evidence and hypotheses is presented as

$$P(h/e) = \frac{P(e/h)P(h)}{P(e)} \qquad [3]$$

This form of Bayes' theorem, while true, often leads to complications when trying to evaluate the probability of the evidence. There is, however, a way to avoid having to estimate that probability. What we can do is to consider *odds* that the hypothesis is true. These odds are the probability the hypothesis is true given the evidence divided by the probability that this hypothesis is false given the evidence – that is, by the ratio $P(h/e)/P(-h/e)$. Once we know the odds, it is trivial to compute the probability. The advantage of considering odds is that the denominator in Bayes' theorem cancels out when we compute these odds. That is

$$\frac{P(h/e)}{P(-h/e)} = \frac{P(e/h)P(h)}{P(e/-h)P(-h)} \qquad [4]$$

Now we are in a position to categorize the most common forms of representative thinking. Pseudodiagnosticity refers to making an inference about the validity of hypothesis h on the base of evidence e without considering hypothesis $-h$. Another way of stating pseudodiagnosticity is that it involves considering only the numerator of the first term on the right-hand side in eqn [4]. People do that when they state that a bit of evidence is 'consistent with' or 'typical of' some hypothesis without concerning themselves about alternative hypotheses, or in particular the negation of the hypothesis. For example, in attempting to diagnose whether a child has been sexually abused, alleged experts in court often refer to

symptoms 'typical' of such abuse – without concerning themselves with how typical these symptoms are of children who have *not* been abused, or the frequency with which children have been sexually abused.

Another type of representative thinking involves considering the probability of the evidence given the hypothesis or hypotheses without looking at the second terms in eqn [4], that is, the prior odds. The reason that these odds are important is that they yield the *extent* of the evidence and hypotheses considered. For example, being a poor speller may be evidence of dyslexia, in the sense, that it has a very high probability given dyslexia. However, in order to diagnose dyslexia on the basis of poor spelling, we have to know something about the base rates of poor spelling and the base rates of dyslexia in the population from which the person whom we wish to diagnose was chosen.

Dilution effects occur when evidence that does not distinguish between hypotheses in fact influences people to be less convinced of a most likely hypothesis; the problem is similar to that found in pseudodiagnosticity in that people do not realize that evidence that is not very likely given the hypothesis may be equally unlikely given the negation of that hypothesis, but may in fact believe a hypothesis less as a result of collecting evidence that is unlikely if it is true. Dilution is simply the converse of pseudodiagnosticity.

Finally, it is possible to describe *availability* biases as well by eqn [4]. People believe that they are sampling evidence given the hypothesis, when, in fact, they are sampling this evidence given the hypothesis *combined with* the manner in which they are sampling. For example, when private practice clinical psychologists claim that they are sampling characteristics of people who fall into a certain diagnostic category on the basis of their experience, what they are really sampling is people who fall in that category *and who come to them*. Similarly, when we sample our beliefs about 'what drug addicts are like,' most of us are sampling on the basis of how the media present drug addicts – both in 'news' programs and in dramatizations (Dawes, 1994b). Doctors often sample on the basis of their contact with addicts when these addicts are ill, perhaps gravely so, while police are often sampling on the basis of their experience with these same addicts during arrests and other types of confrontation. It is not surprising, then, that doctors are in favor of a 'medical' approach to drug addiction including such policies as sterile needle exchanges, while police are in favor of much more punitive policies. Both are sampling evidence *combined with* their exposure to it.

All these anomalies have been demonstrated experimentally. It is important to point out, however, that the investigation of these anomalies did not spring simply from understanding Bayes' theorem and then from creating very clever experimental situations in which subjects' inferences systematically violate it. The motive to study these anomalies of judgment arises from having observed them on a more informal basis outside the experimental setting – and trying to construct an experimental setting, which yields a greater measure of control, that will allow them to be investigated in a systematic manner. The reader is referred, for example, to the essay of Meehl (1977) or the book of Dawes (1994a) for descriptions of these biases in the clinical judgment of professional psychologists and psychiatrists who rely on their own 'experience' rather than (dry, impersonal) 'scientific' principles for diagnosis and treatment.

Analyzing an Important Example

This section ends with a discussion of pseudodiagnosticity, a bias that is prevalent in 'expert' proclamations encouraging 'child sex abuse hysteria' (Dawes, 2001). The main problem here is that hypotheses are not compared: instead, single hypotheses are evaluated in terms of the degree to which evidence is 'consistent with' them; in addition, evidence is often *sought* in terms of its consistency with or inconsistency with 'favorite hypotheses' – rather than in terms of its ability to distinguish *between* hypotheses. This type of pseudodiagnosticity has made its way into the legal system, where experts are allowed to testify that a child's recanting of a report of sexual abuse is 'consistent with' the 'child sexual abuse accommodation syndrome' (Summit, 1983). The finding is that many children who are *known* to have been sexually abused deny the abuse later (recant), therefore, the probability of the evidence (the child recants) given the hypothesis (actual abuse) is not as low as might be naively assumed; therefore, recanting is 'consistent with' having been abused (i.e., can be considered part of a 'syndrome' of accommodation to abuse).

The problem with this pseudodiagnostic reasoning is that it compares the probability of the evidence given the hypothesis to the probability of the *negation of the evidence* given the hypothesis, whereas a rational comparison is of the probability of the evidence given the hypothesis to the probability of the evidence given the *negation of the hypothesis*. When considering this latter comparison, we understand immediately that the recanting would be diagnostic of actual abuse only if the probability of recanting given actual abuse were *higher* than the probability of recanting given such abuse had not occurred – a highly implausible (not to mention paradoxical) conclusion.

Such pseudodiagnostic reasoning is involved in other disasters as well, for example, the explosion of the US Space Shuttle Challenger on 22 January 1986. When considering the possibility that cold temperatures might cause the O-rings to malfunction, "the worried engineers were asked to graph the temperatures at launch time for the flights in which problems have occurred" (Russo and Schoemaker, 1989: p. 197). Thus, these engineers attempted to evaluate the hypothesis that there would be O-ring problems by asking what the temperature was given the existence of these problems. As indicated in **Figure 1(a)** (Figure 6 in Russo and Schoemaker 1989: p. 198), there appeared to be no relationship. When, however, the temperature of launches in which there were *no* problems were considered, a very clear relationship between problems and temperature is evident (see **Figure 1(b)**, from Russo and Schoemaker 1989: Figure 7, p. 198.)

Moreover, people actively seek evidence compatible or incompatible with a hypothesis rather than evidence that distinguishes between hypotheses, as has been extensively studied by Doherty and his colleagues (see, for example Doherty et al., 1979). Consider, for example, subjects who are asked to play the role of medical students (and actual medical students prior to specific training, see Wolf et al., 1985) who must

Figure 1 Partial and total analyses of the relationship between (a) data reviewed prior to launch and (b) the full story from past flights. Source: Russo J.E., Schoemaker P.J.H., 1989. Decision Traps: Ten Barriers to Brilliant Decision Making and How to Overcome Them. Simon and Schuster, New York, pp. 197–198.

determine whether patients have one of two conditions. The conditions are explained, and subjects are told that a patient has two symptoms. The judges are then presented with the conditional probability of one of these symptoms given one of the diseases (e.g., that it is very likely that the patient has a high fever given the patient has meningitis). They can then choose to find out the probability of the other symptom given the same disease, the probability of the first symptom given the second disease, or the probability of the second symptom given the second disease. While virtually no subjects choose a different symptom and a different disease, the majority choose to find the probability of the *second* symptom given the first disease (the 'one that is focal' as a result of being told the first symptom). But for all these subjects know, of course, the first symptom may be more or less typical of the *alternative disease*, as may the second symptom. Finding out that the probability of these two symptoms given only one disease in no way helps to distinguish between that disease and some other. *Of course, in real medical settings doctors may have prior knowledge of these other disease/symptom relationships,* but because the diseases are not even identified in the current setting, such knowledge would be of no help.

Occasionally, pseudodiagnosticity has been confused with what has been termed a 'confirmation bias' – that is, a desire to search for evidence that is very probable given a focal hypothesis. As Fischhoff and Beyth-Marom (1983), Trope and Bassok (1982), and Skov and Sherman (1986) point out, however, such a search does not necessarily imply pseudodiagnosticity (or any other particular irrationality) because it may be possible that the evidence is *not* found – that is, that instead of finding the anticipated evidence, the diagnostician finds its negation. In fact, Skov and Sherman (1986) demonstrate that in searching for evidence – at least in their experimental context – subjects often became quite rational *when they are informed of the conditional probabilities*. The irrationality occurs in the search for which probabilities to seek, and in 'jumping' to a conclusion on the basis of only one probability (i.e., on the basis of the first term in the numerator in the odds form of Bayes' theorem).

The cognitive explanation of pseudodiagnosticity and the other heuristic-based biases covered in the section is simple. People often think by association; in fact, whole computer programs have been built to simulate human judgment on the basis of 'matching' characteristics to schemas. The point of pseudodiagnosticity is that only one 'schema' (i.e., hypothesis) is considered, whereas *coherent diagnostic judgment is always comparative*. In fact, all the biases covered here are based on associational thinking, whereas clear normative probabilistic thinking always involves comparisons.

Summary and Implications

When we deal with probabilistic situations in everyday life, we can often 'muddle through,' but occasionally not appreciating the comparative nature of valid probabilistic thinking can lead to judgmental disasters. Similarly, experience with games of chance can lead to some pretty good intuitive estimations of the likelihood of various payoffs, but once again there can be systematic biases, such as belief in the gambler's fallacy. Explicit probabilistic thinking has developed in our cultures only in the last 500 years or so, and in the last 150 years or so it has become increasingly important in both scientific reasoning and in our day-to-day living – and even in legal contexts (where as jurors we may be asked to judge the liability of a particular company by comparing the probability of developing cancer among those exposed to it or its product as opposed to the 'base rate' probability, or may be asked to evaluate what an expert witness states about the relationship between a symptom and a diagnosis). Here, if we rely on our intuitive grasp of probabilities, we often find that we have systematic biases, much as novice swimmers may attempt to keep their heads above water and thereby drown. These biases – which have been briefly described and cataloged in this article – involve explicitly defined deviations from the conclusions of valid probabilistic reasoning, which follow from the simplest forms of Bayes' theorem. They are not random deviations, which could be modeled as analogous to an engineering context involving a 'signal' plus 'noise.'

Of course, we are also capable of precise probabilistic thinking – just as swimmers are capable of assuming a horizontal position in the water and consequently not drowning. The point is, however, that when we deviate from the rules ('axioms') of probability theory or from coherent judgments, these deviations follow the patterns described here – as has been documented in everyday observation and studied experimentally by those advocating the 'heuristics and biases' approach to such judgment. For a greater elaboration of this approach than is found here, see the chapters in Kahneman et al.'s book *Judgment Under*

Uncertainty: Heuristics and Biases (1982). These systematic departures themselves in turn may be connected to thinking in terms of associations, whereas good probabilistic judgment always requires comparative thinking.

Abstract

The central philosophical issue involving probability concerns the interpretation of ordinary probability claims such as 'there is a 30% probability that it will rain today.' *Epistemic* interpretations of probability understand this to be a claim about belief under uncertainty: it describes the extent to which a certain type of rational agent would (or ought to) believe that it will rain, given the available evidence. Epistemic interpretations include the *Classical*, *Subjective*, and *Logical* Interpretations. *Objective* interpretations of probability read the claim as describing some quantifiable feature of the objective world, sometimes called 'chance.' The concept of chance is thought by some to be intimately connected with *indeterminism*. A system is indeterministic if its later states are not determined by its earlier states in conjunction with the relevant *laws* of evolution. Many objective interpretations of probability invoke the notion of *relative frequency*: the probability of an outcome on a trial of a particular type is thought to be related to the relative frequency with which outcomes of that type do in fact occur on trials of that type. Objective interpretations of probability include the Finite Relative Frequency, Hypothetical Limiting Relative Frequency, Propensity, Best System, and Theoretical Role interpretations.

The central philosophical issue involving probability concerns the interpretation of ordinary probability claims, such as 'there is a 30% probability that it will rain today.' *Epistemic* interpretations of probability understand this to be a claim about belief under uncertainty: it describes the extent to which a certain type of rational agent would (or ought to) believe that it will rain, given the available evidence. *Objective* interpretations of probability read the claim as describing some quantifiable feature of the objective world, sometimes called 'chance.' The concept of chance is thought by some to be intimately connected with *indeterminism*. A variety of epistemic and objective interpretations of probability will be discussed below.

The Problem of the Interpretation of Probability

The problem of the interpretation of probability can be posed using a familiar example: what does a meteorologist *mean* when he or she says that there is a 30 percent probability of rain on a given day? To give an account of what a proposition means is to say what must be the case in order for the proposition to be true. If the meteorologist says that it *will* rain, this assertion is true if and only if it does rain. Whether it rains or not, however, neither outcome by itself renders the *probabilistic* claim true. So what must be the case in order for this claim to be true?

An adequate solution to this problem must provide some way of making sense of the numerical values that appear in probability claims (and must do so in such a way that those values are in accord with the basic principles of probability – see Probability Theory: Formal). The claim that 30 percent of the balls in a given urn are blue has a well-understood meaning: the number of blue balls in the urn, divided by the total number of balls in the urn, is equal to 0.3. In the case of the weather report, however, no comparable formula is immediately available.

Proposed interpretations of probability tend to fall within one of two broad camps, *objective* (or *empirical*) and *epistemic* (or *subjective*) interpretations. Objective interpretations interpret probability claims as describing some feature of the world. Epistemic interpretations of probability, by contrast, interpret probability claims as claims about the extent to which the claim is or ought to be believed. Note that this standard terminology is somewhat misleading: some epistemic interpretations (such as the logical interpretation) take probabilities to be objective in the sense that they do not vary from person to person. The various interpretations of probability canvassed below are often presented as *rivals*, but it may be more appropriate to think of them as complementary. Most researchers who have grappled with interpretive issues have been of the opinion that the concept of probability has both an objective and an epistemic dimension. Accordingly, philosophers often talk of 'objective probabilities' and 'epistemic probabilities.' Objective probabilities are sometimes called 'chances.'

Philosophers (as well as many philosophically minded statisticians) have become interested in the problem of interpretation of probability in part because of the ubiquity of probability claims in science as well as ordinary life, and in part because of the utility of probability theory in analyzing a variety of concepts of interest to philosophers, such as causation (see Causation: Physical, Mental, and Social), confirmation of hypotheses by evidence (see Atomism and Holism: Philosophical Aspects), and rationality (see Rational Choice Explanation: Philosophical Aspects).

This article will focus on the philosophical, rather than the mathematical, dimensions of the problem of interpreting probability. Readers interested in this topic would also do well to read the article on *Probability: Interpretations*. Other surveys of this topic include Salmon (1967), Sklar (1993), and Howson (1995).

Determinism and Chance

In a famous thought experiment, the French physicist Pierre Simon de Laplace (1819) imagined a demon who could

observe the exact position and momentum of every particle in the universe at a given time. Such a demon could plug this information into Newton's equations of motion and predict the state of the universe at all future times. In this thought experiment, Laplace was articulating the concept of *determinism*. A system is *deterministic* if its state at a given time, together with the laws of evolution for that system (see Causes and Laws: Philosophical Aspects), uniquely determine the state of the system at later times. For Laplace, determinism meant that all *objective* probabilities would have to have values of zero or one. Laplace thus thought that probabilistic claims, such as the meteorologist's prognostication described above, reflect human ignorance about which outcome is determined to occur.

At present, there is good reason to believe that certain physical systems described by *quantum mechanics* behave indeterministically. For example, if a vertically polarized photon strikes a polarizer that is oriented with an angle of θ, quantum theory entails that the photon has a probability of $\cos^2\theta$ of passing through. According to the orthodox interpretation of quantum theory (which is not uncontroversial), this probability is *irreducible*: there is no further fact about the photon that determines what it will do on this occasion. If this is correct, then the probability value $\cos^2\theta$ does not merely reflect human ignorance about what the photon will do: it is an objective feature of the world. (For a thorough discussion of philosophical issues involving determinism, see Earman (1986).) One important philosophical issue is whether only such irreducible probabilities are genuine chances. If so, then it would be safe to infer that *none* of the probability claims made within the social sciences describe genuinely objective probabilities.

The word 'chance' is also sometimes used as a singular noun to refer to a chance that is not equal to zero or one. For example, the thesis of determinism is sometimes expressed by saying that there is no genuine chance in the world; 'the USA soccer team has a chance of winning the next world cup' says that the chance of their winning is greater than zero and less than one; to 'take a chance' is to embark on a venture that has a chance of success that is greater than zero but less than one; and so on.

Epistemic Probability

Laplace claimed that probability claims do not describe objective features of the world, but the state of human knowledge (and ignorance). Epistemic interpretations of probability all share this general feature.

The Classical Interpretation

If asked the probability of rolling an odd number on a six-sided die, most people would unhesitatingly respond with the answer one-half: there are six possible outcomes of the die roll, three of which are odd. This illustrates the *classical interpretation* of probability, often associated with Laplace (1819). According to this interpretation, the possible outcomes of a particular trial are divided into 'equally possible' cases, and the probability of outcome F on a particular trial is equal to the number of such cases in which F is true, divided by the total number of possible cases. Which cases are equally possible is determined by the *Principle of Indifference*, which states that two cases are equally possible in the absence of any reason to prefer one outcome over the other.

There are a number of difficulties with the principle of indifference. When the weather reporter claims that the probability of rain is 0.3, there seem to be at least two different types of outcome (rain and no rain) but it is hard to see what the 10 equally possible outcomes (three of which involve rain) could be. Even in much simpler cases, the principle of indifference is not precise enough to specify the equally possible cases. An urn contains both red balls and blue balls; some of the red balls are light red, and some are dark red. What is the probability that the next ball drawn is blue: are there two equally possible cases (red and blue) or three (light red, dark red, and blue)? This problem is further exacerbated when there are infinitely many possible outcomes.

Subjective Interpretations

According to the subjective interpretation of probability (whose proponents are variously called subjectivists' personalists, or Bayesians), probability measures the degrees of belief or *credences* of a certain type of idealized rational agent. Subjectivists regard probability theory as analogous to *formal logic*. Logic alone never tells an agent whether to believe a proposition, but it does require that an agent's beliefs be consistent with one another. For example, the rules of logic forbid an agent to believe 'it will rain today,' 'if it rains today, it will not snow today,' and 'it will snow today' at the same time. According to subjectivists, probability theory is an extension of logic that allows an agent to have degrees of confidence in a proposition that range in value between zero and one. Probability theory alone will not tell the agent how much confidence to place in the proposition 'it will rain today,' but rather imposes a consistency-like constraint (usually called *coherence*) on the totality of the agent's degrees of belief.

The numerical value of an agent's degree of belief in some proposition is connected with the agent's evaluation of bets on the truth of that proposition. For example, if an agent has a degree of belief of 0.3 for the proposition 'it will rain today,' that means that he or she would find a bet on rain at 3:7 odds – a bet that costs the agent three units, and buys a chance to win 10 units (for a profit of seven units) if it rains – to be fair. This connection between degrees of belief, utility, and evaluation forms the foundation of a theory of rational choice wherein an agent always acts so as to maximize expected utility (see Rational Choice Explanation: Philosophical Aspects; Elicitation of Probabilities and Probability Distributions).

This connection between degrees of belief and evaluation is often deployed in arguments that rational degrees of belief conform to the formal rules of probability (see Probability Theory: Formal). When an agent's degrees of belief conform to the probability calculus, then his or her overall system of evaluations will have a number of desirable features. For example, Ramsey (1926) showed that having one's degrees of belief conform to the rules of probability is a necessary condition for having one's overall system of *preferences* satisfy a set of plausible constraints. One such constraint is transitivity: if the agent prefers A to B and B to C, then the agent

prefers A to C. A second class of results comprises the so-called *Dutch Book* theorems. (See, for example, de Finetti, 1964 and Kemeny, 1955.) These results show that if and only if an agent's degrees of belief violate the rules of probability, the agent will be vulnerable to a 'Dutch Book.' A Dutch Book is a system of bets such that the agent finds each individual bet fair, but where the agent is guaranteed of suffering a net loss no matter what the outcome. For example, a bet on heads at 2:1 odds together with a bet of equal stakes on tails at 2:1 odds would constitute a Dutch Book, for the agent purchasing the two bets would be guaranteed of losing 2 units on one bet, and winning 1 unit on the other. (For more details, *see* Probability: Interpretations.)

The requirement that rational degrees of belief satisfy the rules of probability theory is a *synchronic* constraint on one's degrees of belief: it concerns an agent's degrees of belief at one particular time. Some subjectivists impose a further *diachronic* constraint on allowable methods for changing one's degrees of belief over time. Suppose that a rational agent's degrees of belief at some particular time are represented by the probability function P. If the agent then acquires some new piece of information I, then the agent's new degree of belief in any proposition A is equal to the *conditional probability* $P(A/I)$ (see *Probability: Formal* for the definition of conditional probability). This rule of updating degrees of belief by *conditionalizing* can also be motivated by a form of Dutch Book argument (proved by David Lewis and reported in Teller (1973)).

This rule for changing degrees of belief has been championed by so-called *Bayesians* as a theory of confirmation. According to this theory, a hypothesis H is confirmed or supported by a piece of evidence E just in case conditionalizing on E increases the probability of H. This probabilistic approach to confirmation theory has proven to be very fruitful. see also Howson and Urbach (1993).

The various theorems invoked by subjectivists are *formal* results, and there is considerable debate over their interpretation. In particular, there is disagreement about how, or even whether, the Dutch Book theorems really show that coherence or updating by conditionalization are canons of rationality. Critics of subjectivism point out that even an incoherent agent would be capable of following the proofs of these theorems, and hence of foreseeing the dangers of Dutch Books; thus coherence and updating by conditionalization are not really necessary for avoiding financial loss (*see* Howson and Urbach, 1993 for further discussion).

A second focus of criticism is the *subjective* nature of degrees of belief. Rational agents may differ in the degree to which they believe a proposition such as 'it will rain today'; indeed their degrees of belief may range all the way from zero to one. Moreover, the constraints of synchronic coherence plus updating by conditionalization do not rule out the possibility that one's degrees of belief are *dogmatic* in a certain respect. It is consistent with these constraints that an agent have degree of belief of 0.99 that each toss of a given coin will land heads, and after observing a thousand tails in a row, *still* believe that the *next* toss will almost certainly be heads. Subjectivists have been able to prove many interesting results about how an agent's degrees of belief *would* evolve in the face of new evidence *if* the agent's original degrees of belief (or *prior probabilities*) were nondogmatic in various ways (de Finetti's, 1964 representation theorem is one important example), but there is nothing in subjectivism that would *require* the agent to have such nondogmatic prior probabilities. For many, this latitude makes subjective degrees of belief ill-suited as a foundation for theories of rational choice or rational inference.

Logical Interpretations

Logical interpretations aim to avoid the problems of subjectivist interpretations by imposing further constraints on an agent's prior probabilities. Prior probabilities are determined by the logical structure of the space of outcomes, much as they are in the classical interpretation. Unlike the classical interpretation, however, probability assignments can reflect the bearing of evidence that discriminates among the possible outcomes. Thomas Bayes (1763) and Laplace (1819), who are commonly associated with the subjectivist and classical approaches (respectively), both endorsed a version of the logical approach to probability. Twentieth century proponents include Carnap (1950), Jeffreys (1961), and Jaynes (1973).

Logical interpretations of probability inherit many of the difficulties of the classical interpretation discussed above: logical considerations alone do not determine a unique prior probability distribution. Moreover, many of the most plausible candidates for logical probabilities – such as one in which a sequence of coin tosses is *independent and identically distributed* (see Probability Theory: Formal or Distributions, Statistical: Special and Discrete) – turn out to be dogmatic in just the manner described in Section Subjective Interpretations

The Need for Objective Interpretations

Although few would doubt that our ordinary concept of probability has an epistemic dimension, it seems implausible that *all* probability claims can be interpreted epistemically. Consider the claim that a photon has a certain probability of passing through a polarizer; it would be very odd indeed if the truth of this claim (and hence of quantum mechanics) depended on the extent to which some agent(s) may believe that the photon will pass through or on the extent to which available evidence confirms this hypothesis. At best, epistemic interpretations of probability will have to be supplemented by an objective interpretation of at least some probability statements.

Objective Interpretations of Probability

In practice, probabilities are often inferred from frequency data. To estimate the probability that a given coin will land heads when tossed, for example, one could toss it many times and observe the relative frequency with which the coin lands heads. Such relative frequencies are *objective* features of the world. Hence relative frequencies provide a natural resource for objective interpretations of probability claims.

Finite Relative Frequency Interpretation

Perhaps the simplest interpretation of a probability claim would be to understand it as a claim about an actual finite

relative frequency. For example, if a coin were tossed exactly 10 times and then destroyed, resulting in 'heads' on six of those 10 tosses, then the probability that the coin lands heads when tossed would be 0.6. The central difficulty with this definition of probability is that it rules out unrepresentative samples by definition. For example, if a coin is fair, i.e., has a probability of 0.5 of landing heads when tossed, that should not be taken to rule out the possibility of it landing hands on six of the 10 occasions on which it is tossed. According to the finite frequency definition of probability, however, if the probability of heads is 0.5, then *by definition* the coin will land heads on exactly half of its tosses. Thus, while finite relative frequencies provide indispensable evidence for probabilistic claims, probabilities cannot be identified with finite relative frequencies.

Limiting Relative Frequency Interpretation

In order to avoid these problems with finite frequencies, some philosophers have suggested that probabilities be identified with frequencies in an *infinite* sample. If the first n tosses of a coin yields $f(n)$ heads, then the relative frequency of heads in the first n tosses is $f(n)/n$. The *limiting relative frequency* of heads in the infinite sequence of tosses is the limit as n goes to infinity of $f(n)/n$. This approach to interpreting probability was pioneered by Venn (1866); leading twentieth century proponents of this interpretation (hereafter called *frequentists*) include Richard von Mises (1957) and Hans Reichenbach (1949).

One important problem with limiting relative frequencies is that they seldom, if ever, exist: no coin is actually tossed an infinite number of times. Thus the limiting relative frequencies that determine the probability of an outcome are really *hypothetical limiting relative frequencies*: to say that the probability of heads on a toss of a certain coin is 0.5 is to say that *if* the coin were to be tossed an infinite number of times, the limiting relative frequency of heads *would be* 0.5. This is a hypothetical or *counterfactual* claim; by itself, it says nothing about what features of the *actual world* make the probabilistic claim true. The problem of interpretation of counterfactuals is itself a thorny philosophical problem (*see* Counterfactual Reasoning, Qualitative: Philosophical Aspects; Counterfactual Reasoning, Quantitative: Philosophical Aspects).

One important issue that divides frequentists is whether it is possible to ascribe a probability value to the outcome of a single trial. One tradition, following von Mises (1957), views probability as a property of a sequence of trials, or a 'collective.' Any single coin toss belongs to infinitely many different sequences: the sequence of all coin tosses, the sequence of all tosses of that particular coin, the sequence of all tosses of that coin by imparting a particular force from a particular height above the floor, and so on. The limiting relative frequency of 'heads' may be different in each of these sequences. Thus, there is no unique probability of 'heads' on a given toss, but only a probability for 'heads' in a collective of tosses. While frequentists in this tradition deny that there is one privileged sequence of coin tosses, not just any sequence of tosses is fit to bear probability values. For example, if an infinite sequence of coin tosses were to yield an alternating sequence of 'heads' and 'tails,' the relative frequency of 'heads' would be 0.5. The regularity of the pattern of outcomes would nonetheless render this sequence inappropriate for characterizing a probability value. Rather, probabilities are limiting relative frequencies in a *random* sequence of trials. There is no universally accepted mathematical characterization of randomness, although this is currently an area of active research (see Earman 1986, Chap. VIII). For a more detailed exposition of this version of the limiting relative frequency interpretation, see Probability: Interpretations.

One feature of this approach is that it allows chances to take on values other than zero or one even if determinism is true. It may be that on any particular toss of a coin, the linear and angular momentum imparted to the coin together with its height above the floor and so on determine the outcome of the coin toss. Nonetheless, there may be a random sequence of coin tosses where the limiting relative frequency is not equal to zero or one, for the tosses comprising the collective need not be identical with respect to such determining factors.

The relegation of probabilities to properties of collectives would seem to be a drawback of this approach to probability. When deciding whether to bet on a coin toss, or to postpone a picnic, one wants to know the probability of heads *on that particular toss*, or the probability of rain *on this particular day*. Some frequentists, following Reichenbach, believe that it is possible to assign probability values to the outcomes of individual trials. This requires that a choice be made from among all of the sequences to which the trial in question belongs. For example, a particular day belongs in an infinite number of sequences of days, and the limiting relative frequency of rain need not be the same in all of them, so which sequence determines the probability of rain on the day in question? Presumably not just the sequence of all days, for then the probability of rain would not vary from day to day. A natural thought is that what is wanted is a sequence of days *just like this one*. No two days will be exactly alike in *all* respects, however; the best that can be hoped for is a sequence of days that are alike in all *relevant* respects. The key problem, then, is to say what makes some respects of similarity between days relevant and others irrelevant. One detailed proposal is developed in Salmon (1984, Chap. 3).

On this approach, determinism is compatible only with chances of zero or one. Suppose, for example, that on a given day, climactic conditions determine that it will rain. Then the appropriate sequence will presumably consist of days in which the same climactic conditions prevail, and hence the limiting relative frequency of rain within that sequence will be one.

Propensity Interpretation

The propensity interpretation of probability, first introduced by Karl Popper (1959), is motivated by some of the difficulties with the limiting relative frequency interpretation. According to this interpretation, a coin, in conjunction with the conditions in which it is tossed, has a certain *disposition* or *propensity* to land heads. The probability that the coin will land heads is a measure of the strength of this propensity. This propensity is a property of the particular experimental set-up, hence, it is appropriate to assign a probability to an individual trial. Moreover, this propensity provides grounds for the truth of claims about what the coin *would do* if tossed infinitely many times in identical (or relevantly similar) conditions.

While this is certainly a useful way of thinking about single case probabilities within a frequentist framework, critics wonder whether anything has really been added. A coin is about to be tossed: there is some property of this experimental set-up in virtue of which the coin *would* land heads with a certain limiting relative frequency if this experiment were repeated infinitely often; calling this property a 'propensity' of a certain strength does little to indicate just what this property is. Moreover, if propensities are Pnot simply identified with hypothetical limiting relative frequencies, it is hard to see what is supposed to ground the claim that propensities have the mathematical structure of probabilities.

Best System Interpretation

The philosopher David Lewis (1986) has proposed an interpretation according to which an objective probability claim is true when it is entailed by a probabilistic *law* (*see* Causes and Laws: Philosophical Aspects). On this view, objective probability is intimately connected with indeterminism. A probabilistic claim is a law if it belongs to the set of propositions that provides the best overall systematization of the world. In order to be the best systematization, a set of propositions must obtain the optimal balance between informativeness, simplicity, and fit with data. For example, consider the claim that a photon will pass through a polarizer with a probability of $\cos^2\theta$. Although the frequency with which photons do pass through when the experiment is performed may diverge from this number, the probability value is firmly grounded in the principles of quantum mechanics, which overall provides an excellent fit with experimental data, and is a powerful and elegant theory.

Unlike the frequency interpretations, however, the truth conditions for probabilistic claims provided by the best system interpretation are not very precise. It is not clear what makes one set of propositions simpler than another, nor how simplicity is to be balanced against informativeness and goodness of fit.

Theoretical Role Interpretations

One further line of interpretation is influenced by the philosophical school of pragmatism (*see* Pragmatism: Philosophical Aspects). In this approach, objective probability claims are to be understood in terms of their role in our overall conceptual system. In particular, to understand a probability claim is to know what kinds of evidence would support or undermine that claim, and how to act accordingly if one accepts that claim as true. This approach has been developed by Mellor (1971), Skyrms (1980), and Lewis (1986).

Consider an agent whose degrees of belief conform to the rules of probability (see Section Subjective Interpretations), and let *Ch* be a function that assigns numerical values to propositions. The agent takes *Ch* to be objective chance precisely if his or her degrees of belief are guided by beliefs about the values of *Ch*. For example, suppose that the agent believes *Ch* ('it will rain today') to be 0.3. If the agent understands *Ch* to be objective chance, then his or her degree of belief in the proposition 'it will rain today' will also be 0.3. This degree of belief, together with the agent's utility function, can then be used to decide whether or not to postpone a picnic. In this way, then, the agent's beliefs about objective chances influence his or her decisions. Moreover, since objective probability claims are now propositions about which the agent has degrees of belief, the apparatus of Bayesian confirmation theory shows how those degrees of belief will change in the face of new evidence.

This approach has a number of virtues, not least of which is that it explains why objective chances have the formal properties of probability theory: in order for beliefs about chances to guide degrees of belief in the appropriate way, objective chances must have the same formal structure as rational degrees of belief. There is, however, an important drawback to this approach. In analyzing the meaning of objective probability claims in terms of their theoretical role instead of their truth conditions, this account does not answer what many have taken to be the central question of objective probability: what must be the case in the world in order for the (objective) probability of rain to be 0.3?

Conclusion

Interest in the philosophical aspects of probability dates back to the origins of the formal theory of probability in the seventeenth century. Epistemic and frequency interpretations of probability have been around for well over a century. In the second half of the twentieth century, interest in objective interpretations of single-case probabilities has dramatically increased the range of interpretive options available. Given the current lack of consensus, and the increasingly widespread use of probabilistic concepts in both philosophy and everyday life, it is safe to predict that interest in the problem of the interpretation of probability will continue into the twenty-first century.

Abstract

The probability density function is useful for summarizing and exploring a set of data. When the parametric form is unknown, then a nonparametric estimator such as the histogram is appropriate. This article illustrates the presentation of data by the histogram compared to the empirical distribution function. The steps required to construct a histogram are described, and data-based methods to accomplish this task are presented. Finally, the more efficient kernel density estimator is introduced and illustrated with real data.

The probability density function is useful for summarizing and exploring a set of data. When the parametric form is unknown, then a nonparametric estimator such as the histogram is appropriate. This article illustrates the presentation of data by the histogram compared to the empirical distribution function. The steps required to construct a histogram are described, and data-based methods to accomplish this task are presented. Finally, the more efficient kernel density estimator is introduced and illustrated with real data.

Associated with each random variable, X, measured during an experiment is the cumulative distribution function (cdf), $F(x)$. The value of the cdf at $X = x$ is the probability that $X \leq x$. Features in a set of random data may be computed analytically if the cumulative distribution function is known. The probability that a random sample falls in an interval (a, b) may be computed as $F(b) - F(a)$. This formula assumes the values of X are continuous. Discrete random variables taking on only a few values are easy to handle; thus, this article focuses on continuous random variables with at least an interval scale.

The same information may be obtained from the probability density function (pdf), $f(x)$, which equals $\Pr(X = x)$ if X takes on discrete values, or the derivative of $F(x)$ if X is continuous. If either $F(x)$ or $f(x)$ is known, then any quantity of interest such as the variance may be computed analytically or numerically. Otherwise, such quantities must be estimated using a random sample $x_1, x_2, \ldots, x_n$. The relative merits of estimating $F(x)$ vs. $F(x)$ are an important part of this article.

Density estimation takes two distinct forms – parametric and nonparametric – depending on prior knowledge of the parametric form of the density. If the parametric form $f(x|\vec{\theta})$ is known up to the p parameters $\vec{\theta} = (\theta_1, \ldots, \theta_p)$, then the parameters may be estimated efficiently by maximum likelihood or Bayesian algorithms. When little is known of the parametric form, nonparametric techniques are appropriate. The most commonly used estimators are the histogram and kernel methods, as discussed below.

Histograms and CDFs

Grouping and counting the relative frequency of data to form a histogram may be taught at the beginning of every statistics course, but the concept seems to have emerged only in 1662 when John Graunt studied the Bills of Mortality and constructed a crude life table of the age of death during those times of plague (Westergaard, 1968). Today the histogram and its close relative, the stem-and-leaf plot, provide the most important tools for exploring and representing structure in a set of data. Studying the shape of a well-constructed histogram can verify an assumption of normality, or reveal departures from normality such as skewness, kurtosis, or multiple modes. The recent study of the theoretical properties of histograms has led to concrete methods for computing well-constructed figures as discussed below.

With only a random sample of data, the cdf may be estimated by the empirical cdf (ecdf), denoted by $F_n(x)$. The value of the ecdf at x is the fraction of the sample with values less than or equal to x, that is, $\{\#x_i \leq x\}$. Now the probability any one of the x_i is less than x is given by the true cdf at x. Hence, on average, the value of $F_n(x)$ is exactly $F(x)$, and $F_n(x)$ is an unbiased estimator of $F(x)$. The inequality $\{X_i \leq x\}$ is a binomial random variable, so that the variance of $F_n(x)$ may be computed as $F(x)(1 - F(x))/n$. In fact, there is no other unbiased estimator with smaller variance.

The graph of the empirical cdf looks like a staircase function. **Figure 1** displays the ecdf of the treatment times estimated by 33 physicians when presented with a hypothetical patient suffering from extreme migraine headaches (Hebl and Xu, 2000). The dotted line is the cdf of the fitted normal density $N(31.3, 9.9^2)$, which appears to fit reasonably well. **Figure 2** displays a histogram of the same data, which does not appear to be normal after all. Social scientists often are taught to favor the ecdf over the histogram, but in fact aside from computing probabilities, the ecdf is not well-suited for the easy understanding of data.

The probability density function, $f(x)$, carries the same information as the cdf. Since the derivative of the empirical cdf $F_n(x)$ is not well-defined, estimators that rely on grouping have been devised. A convenient interval, (a, b), containing the data is chosen, and subdivided into m 'bins' of equal width $h = (b - a)/m$. The value h is called the bin width (and is often called the smoothing parameter). A 'well-constructed' histogram must specify appropriate values for a, b, h, and m. Given such parameters, the number of samples falling into each of the

Figure 1 Empirical cumulative distribution function of physicians' estimated treatment times for a patient suffering migraine headaches. The dotted line is the cdf of the normal fit.

Figure 2 Frequency histogram of treatment times.

m bins is tallied. Label the m bin counts $\nu_1, \nu_2, \ldots, \nu_m$ from left to right. If the interval (a, b) contains all the samples, then $\sum_{k-1}^{m} \nu_k = n$. A *frequency histogram* is simply a plot of the bin counts, as in Figure 2. Although the values are all multiples of 5 min, the data may be treated as continuous. However, the bin width should only be a multiple of 5 and care should be exercised to choose a and h so that no data points fall where two bins adjoin. Here, $a = 2.5$, $b = 57.5$, and $h = 5$. The histogram suggests a departure from normality in the form of three modes. Re-examine the ecdf in Figure 1 and try to identify the same structure.

A true probability density is a non-negative function that integrates (sums) to 1. Hence, the *density histogram* is a simple normalization of the frequency histogram in the kth bin,

$$\hat{f}(x) = \frac{\nu_k}{nh} \qquad [1]$$

The normalization is important when the data are heavily skewed and unequal bin widths are constructed. In such cases, the interval (a, b) is partitioned into m bins of width $h_1, h_2, \ldots, h_m$. The bin counts $\nu_1, \nu_2, \ldots, \nu_m$ should *not* be plotted as they are not relatively proportional to the true density histogram, which is now given by $f(x)=\nu_k/(nh_k)$ in the kth bin.

Figure 3 Density histogram of the distances of Mark McGwire's 70 home runs in the 1998 season.

Figure 3 displays a density histogram of the distances of the 70 home runs hit by Mark McGwire during his record-setting 1998 American baseball season. A bin width of 20 ft was chosen, and then several adjacent bins were collapsed to make the histogram look unimodal. The long right tail reflects the booming home runs for which McGwire is known.

Bin Width Construction

Rules for determining the number of bins were first considered by Sturges in 1926. Such rules are often designed for normal data, which occur often in practice. Sturges observed that the mth row of Pascal's triangle, which contains the combinatorial coefficients $\binom{m-1}{0}, \binom{m-1}{1}, \ldots, \binom{m-1}{m-1}$, when plotted, appears as an ideal frequency histogram of normal data. (This is a consequence of the central limit theorem for large m.) The sum of these 'bin counts' is 2^{m-1} by the binomial expansion of $(1+1)^{m-1}$. Solving the equation $n=2^{m-1}$ for the number of bins, we obtain Sturges' rule

$$m = 1 + \log_2 n \qquad [2]$$

This rule is widely applied in computer software.

The modern study of histograms began in Scott (1979) and Freedman and Diaconis (1981). The optimization problem formulated was to find the bin width h to make the average value of the 'distance' $\int [\hat{f}(x) - f(x)]^2 \, dx$ as small as possible. The solution for the best bin width is

$$h^* = \left[\frac{6}{\int f'(x)^2 dx}\right]^{1/3} n^{-1/3} \qquad [3]$$

While the integral of the derivative of the unknown density is required to use this formula, two useful applications are available. First, the *normal reference rule* gives

$$h^* = 3.5\sigma n^{-1/3} \qquad [4]$$

since the value of the integral for a normal density is $(4\sqrt{\pi}\sigma^3)^{-1}$. The second application was given by Terrell and Scott (1985) who searched for the 'easiest' smooth density

(which excludes the uniform density) and found that the number of bins in a density should always exceed $\sqrt[3]{2n}$ or that the bin width should always be less than

$$h^* \leq 3.73\sigma n^{-1/3} \qquad [5]$$

These choices are called *oversmoothed rules*, as the optimal choices will never be more extreme for other less smooth densities. Notice that the normal reference rule is very close to the upper bound given by the oversmoothed rule. For the McGwire data, the oversmoothed rule gives $h^* \leq 42'$.

More sophisticated algorithms for estimating a good bin width for a particular data set are described in Scott (1992) and Wand (1997). For example, a cross-validation algorithm (Rudemo 1982) that attempts to minimize the error distance directly leads to the criterion

$$\mathrm{CV}(h) = \frac{2}{(n-1)h} - \frac{n+1}{(n-1)n^2 h}\sum_{k=1}^{m} v_k^2 \qquad [6]$$

The bin counts are computed for a selection of bin widths (and bin origins), the criterion computed, and the minimizer chosen, subject to the over-smoothed bound. The criterion tends to be quite noisy and Wand (1997) describes alternative plug-in formulae that can be more stable.

All of these rules give bin widths which shrink at the rate $n^{-1/3}$ and give many more bins than Sturges' rule. In particular, most computer programs give histograms which are *oversmoothed*. The default values should be overridden, especially for large datasets. Similarly, the error of the best histogram decreases to zero at the rate $n^{-2/3}$, which can be improved to $n^{-4/5}$ as described below. However, the histogram remains a powerful and intuitive choice for density estimation and presentation.

Advanced Algorithms

Density estimators with smaller errors are continuous functions themselves. The easiest such estimator is the frequency polygon, which connects the midpoints of a histogram. A separate error theory exists. For example, the oversmoothed bin width for a histogram from which the frequency polygon is drawn is given by

$$h^* \leq 2.33\sigma n^{-1/5}$$

Note that this bin width is wider than the rules for the histogram alone.

Many other estimators exist, based on splines, wavelets, Fourier series, or local likelihood, but all are closely related to the kernel estimator of Rosenblatt (1956) and Parzen (1962), which is described here. The kernel can be any probability density function, but the normal density is a common and recommended choice. Here the smoothing parameter h is the standard deviation of the normal kernel. If the normal density $N(\mu,\sigma^2)$ at a point x is denoted by $\phi(x|\mu, \sigma)$, then the kernel estimator is

$$\hat{f}_K(x) = \frac{1}{n}\sum_{i=1}^{n}\phi(x|x_i, h)$$

This form shows that the kernel estimator is a mixture of normal densities which are located at the data points. The oversmoothed smoothing parameter value is

$$h^* \leq 1.14\sigma n^{-1/5}$$

An example is given below.

Visualization

The primary uses of density estimation are to display the structure in a set of data and to compare two sets of data. The histogram is adequate for the first task, but overlaying two histograms for comparison is difficult to interpret. The continuity and improved error properties of the kernel estimators excel for this purpose.

In the great home run race of 1998, Sammy Sosa finished second with 66 home runs. Figure 4 displays the empirical cdfs of the distances for the two home run kings (Keating and Scott 1999). This graph clearly shows that McGwire hits longer home runs than Sosa at every distance. In Figure 5, kernel estimates of the McGwire and Sosa data with h=10 are overlaid. The possible structure in these data is reinforced by the similarity of the two densities. Each has two primary modes at 370 ft and 425 ft, with smaller feature around 475 ft. In addition, McGwire's density clearly shows the right tail of his longest homers. In contrast, the modes in the original histogram of Figure 3 did not appear convincing, and were eliminated by locally adjusting the bin widths. The continuity of the kernel and other estimators makes the assessment of modes much easier.

Multivariate Densities

Histograms can be constructed in the bivariate case and displayed in perspective, but cannot be used to draw contour plots. Kernel methods are well-suited for this purpose. Given a set of data $(x_1, y_1), \ldots, (x_n, y_n)$, the bivariate normal kernel estimator is given by

$$\hat{f}_K(x,y) = \frac{1}{n}\sum_{i=1}^{n}\phi(x|x_i, h)\phi(y|y_i, h)$$

Figure 4 Empirical cumulative distribution functions of the distances of Mark McGwire's 70 (solid line) and Sammy Sosa's 66 (dotted line) home runs in 1998.

Figure 5 Kernel density estimates of the distances of Mark McGwire's 70 (solid line) and Sammy Sosa's 66 (dotted line) home runs in the 1998 season. McGwire's data are plotted below the horizontal line and Sosa's above.

A different smoothing parameter can be used in each variable.

For three- and four-dimensional data, the kernel estimator can be used to prepare advanced visualization renderings of the data. Scott (1992) provides an extension set of examples.

Other Materials

A number of other monographs exist that delve into various aspects of nonparametric approaches. A thorough survey of all topics by top researchers is contained in Schimek (2000). Early works popularizing these ideas include Tapia and Thompson (1978) and Silverman (1986). Wand and Jones (1994) and Simonoff (1996) focus on kernel methods. Fan and Gijbels (1996) and Loader (1999) focus on local polynomial methods. General smoothing ideas are discussed by Härdle (1991) and Bowman and Azzalini (1997). Many other excellent references may be followed in these books.

Abstract

Probability theory is a branch of mathematics that evolved from the investigation of social, behavioral, and physical phenomena that are influenced by randomness and uncertainty. This article begins its survey of probability theory with a discussion of the impact of A.N. Kolmogorov's framework for the mathematical understanding of probability and the role that his axioms had in transforming probability from a modeling art to a mathematical science. The survey then discusses the important notion of a random variable, and the tools for describing such variables, including means, variances, distribution functions, densities, and the fundamental property of independence. The article also discusses the law of large numbers – the mathematical result that underlies the popular 'law of averages' and the central limit theorem – the mathematical result that suggests why the 'bell curve' is present in many social and physical phenomena. The article concludes by reviewing sources of further information on probability theory.

Probability theory is a branch of mathematics that has evolved from the investigation of social, behavioral, and physical phenomena that are influenced by randomness and uncertainty. For much of its early life, probability theory dealt almost exclusively with gambling games, and, even though there were important contributions made by such distinguished mathematicians as Pierre de Fermat, Blaise Pascal, and Pierre-Simon de Laplace, the field lacked respectability and failed to attract sustained attention.

One cause of the slow development of probability theory in its early days was the lack of a widely accepted foundation. Unlike the geometry of Euclid, or even the analytical investigations of Newton and Leibnitz, the theory of probability seemed to be eternally tied to the modeling process. In this respect, probability theory had greater kinship with the theories of heat or elasticity than with the pristine worlds of geometry or algebra.

Over time, foundations for probability were proposed by a number of deep thinking individuals including von Mieses, de Finetti, and Keynes, but the approach that has come to be the most widely accepted is the one that was advanced by Andrey Nikolayevich Kolmogorov (1933).

Kolmogorov's approach to the foundations of probability theory developed naturally from the theory of integration that was introduced by Henri Lebesgue and others during the first two of decades of the twentieth century. By leaning on the newly developed theory of integration, Kolmogorov demonstrated that probability theory could be simply viewed as another branch of mathematics. After Kolmogorov's work, probability theory had the same relationship to its applications that one finds for the theory of differential equations. As a consequence, the stage was set for a long and productive mathematical development.

To be sure, there are some philosophical and behavioral issues that are not well addressed by Kolmogorov's bare-bones foundations, but over the years, Kolmogorov's approach has been found to be adequate for most purposes. The Kolmogorov axioms are remarkably succinct, yet they have all the power that is needed to capture the physical, social, and behavioral intuition that a practical theory of probability must address.

Kolmogorov's Axiomatic Foundations

Central to Kolmogorov's foundation for probability theory was his introduction of a triple $(\Omega, \mathscr{F}, P)$ that is now called a probability space. The triple's first element, the 'sample space' Ω, is only required to be a set, and on the intuitive level, one can think of Ω as the set of all possible outcomes of an experiment. For example, in an experiment where one rolls a traditional six-faced die, then one can take $\Omega = \{1, \ldots, 6\}$.

The second element of Kolmogorov's probability space is a collection $\mathscr{F}$ of subsets of Ω that satisfy three basic consistency properties that will be described shortly. On the intuitive level, one can think of the elements of $\mathscr{F}$ as 'events' that may occur as a consequence of the experiment described by $(\Omega, \mathscr{F}, P)$. Thus, to continue with the example of rolling a die, the set $A = \{1, 3, 5\} \subset \Omega$ would correspond to the event that one rolls an odd number.

Two of the three consistency properties that Kolmogorov imposes on the $\mathscr{F}$ are quite trivial. First, $\mathscr{F}$ is required to contain Ω. Second, $\mathscr{F}$ must be closed under complementation; so, for example, if $A \in \mathscr{F}$ then $A^c \in \mathscr{F}$ where $A^c = \{\omega : \omega \in \Omega$ and $\omega \notin A\}$. This third condition is only a bit more elaborate; the collection $\mathscr{F}$ must be closed under countable unions. Thus, if $A_k \in \mathscr{F}$ for $k = 1, 2, \ldots$, then one requires that the union $A_1 \cup A_2 \cup \ldots$ of all the events in the countable set $\{A_k : 1 \leq k < \infty\}$ must again be an element of $\mathscr{F}$.

The most interesting element of Kolmogorov's triple $(\Omega, \mathscr{F}, P)$ is the 'probability measure' P. Formally, P is just a function that assigns a real number to each of the elements of $\mathscr{F}$, and, naturally enough, one thinks of $P(A)$ as the probability of the event A. Thus, one can specify a probability model for the outcome of rolling a fair die, by 'defining' P for $A \subset \Omega$ by $P(A) = 1/6|A|$, where $|A|$ denotes the number of elements of the set A.

For sample spaces Ω that are not finite, more care is required in the specification of the probability measures P. To deal with general Ω, Kolmogorov restricted his attention to those P that satisfy three basic axioms:

Axiom 1. For all $A \in \mathscr{F}$, one has $P(A) \geq 0$.
Axiom 2. $P(\Omega) = 1$.

Axiom 3. For any countable collection $\{A_k \in \mathscr{F}: 1 \leq k < \infty\}$ with the property that $A_j \cap A_k = \Phi$ for all $j \neq k$, one has

$$P\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} P(A_i)$$

Axioms 1 and 2 just reflect the intuitive view that $P(A)$ measures the frequency with which A occurs in an imagined sequence of repetitions of the experiment $(\Omega, \mathscr{F}, P)$. For most mathematicians, axiom 3 also just reflects the most basic intuition about the way probabilities should behave. Nevertheless, axiom 3 is more subtle because it deals with an infinite collection of sets, and in some ways, such collections are outside of our direct experience. This has lead some philosophers to examine the possibility of avoiding Kolmogorov's third axiom, and over the years various attempts have been made to replace Kolmogorov's third axiom with the simpler assumption of 'finite additivity.'

Random Variables

In most applications of probability theory, the triple $(\Omega, \mathscr{F}, P)$ that gives life to probability as a rigorous mathematical subject is almost invisible. In practice, builders of probability models take advantage of various shortcuts that have the effect of keeping the probability triple at a respectful distance. The most important of these shortcuts is the notion of a 'random variable.'

On the intuitive level, a random variable is just a number that depends on a chance-driven experiment. More formally, a random variable X is a function from Ω to the real numbers with the property that $\{\omega: X(\omega) \leq t\} \in \mathscr{F}$ for all t. What drives this definition is that one inevitably wants to talk about the probability that X is less than t, and for such talk to make sense under Kolmogorov's framework, the set $\{\omega: X(\omega) \leq t\}$ must be an element of $\mathscr{F}$. Random variables make the modeler's job easier by providing a language that relates directly to the entities that are of interest in a probability model.

The Distribution Function and Related Quantities

There are several ways to specify the basic probabilistic properties of a random variable, but the most fundamental description is given by the 'distribution function' of X, which is defined by $F(t) = P(X \leq t)$. Knowledge of the distribution function tells one everything that there is to know about the probability theory of the random variable. Sometimes it even tells too much.

The knowledge one has of a random variable is often limited, and in such cases it may be useful to focus on just part of the information that would be provided by the distribution function. One common way to specify such partial information is to use the 'median' or the 'quantiles' of the random variable X. The median is defined to be a number m for which one has $P(X < m) \leq 1/2 \leq P(X \leq m)$. Roughly speaking, the median m splits the set of outcomes of X into two halves so that the top half and the bottom half each have probability that is close to one-half.

The quantile x_p does a similar job. It splits the possible values of X into disjoint sets, so that one has $P(X < x_p) \leq p \leq P(X \leq x_p)$. When $p = 1/2$, the quantile x_p reduces to the median, and, when $p = 1/4$ or $p = 3/4$, then x_p is called the 'lower quartile,' or the 'upper quartile,' respectively.

Mass Functions and Densities

If a random variable X only takes values from a finite or countable set S, then X is called a 'discrete' random variable. In such cases, one can also give a complete description of the probabilistic properties of X by specification of the 'probability mass function,' which is defined by setting $f(x) = P(\{x\})$ for all $x \in S$. Here, one should note that the probability mass function f, permits one to recapture the distribution function by the relation

$$F(t) = \sum_{x \leq t, x \in s} f(x) \quad \text{for all } t$$

There are many important random variables whose values are not confined to any countable set, but for some of these random variables, there is still a description of their distribution functions that is roughly analogous that provided for discrete random variables. A random variable X is said to be 'absolutely continuous' provided that there exist a function f such that the distribution function of X has a representation of the form

$$F(t) = \int_0^t f(x)\mathrm{d}x \quad \text{for all } t$$

The function f in this representation is called the 'density' of X, and many random variables of practical importance have densities. The most famous of these are the 'standard normal' (or, 'standard Gaussian') random variables that have the density

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \quad \text{for all } -\infty < x < \infty$$

which has a key role in the Central Limit Theorem that will be discussed shortly.

Much of the theory of probability can be developed with just the notion of discrete or absolutely continuous random variables, but there are natural random variables that do not fit into either class. For this reason, the distribution function remains the fundamental tool for describing the probabilities associated with a random variable; it alone is universal.

Mathematical Expectation: A Fundamental Concept

If X is a discrete random variable, then its 'mathematical expectation' (or just expectation, for short) is defined by

$$E(X) = \sum_{x \in s} x f(x)$$

where f is the probability mass function of X. To illustrate this definition, one can take X to be the outcome of rolling a fair die, so that $f(x) = 1/6$ for all $x \in S = \{1, 2, \ldots, 6\}$ and

$$E(X) = 1\cdot\frac{1}{6} + 2\cdot\frac{1}{6} + \cdots + 6\cdot\frac{1}{6} = \frac{7}{2}$$

In a way that is parallel – yet not perfectly so – the expectation of an absolutely continuous random variable X is defined by the integral

$$E(X) = \int_{-\infty}^{\infty} x f(x)\mathrm{d}x$$

Here one needs to work a bit harder to illustrate the definition. Consider, for example, an experiment where one chooses a number at random out of the unit interval [0, 1]. From the intuitive meaning of the experiment, one has $P(A) = a$ for $A = [0, a]$, and, from this relationship, one can calculate that the density function for X is given by $f(x) = 1$ for $x \in [0, 1]$ and by $f(x) = 0$ otherwise. For the density f, one therefore finds that

$$E(X) = \int_{-\infty}^{\infty} x f(x)\mathrm{d}x = \int_{0}^{1} x\cdot 1\ \mathrm{d}x = \frac{1}{2}$$

From this formula, one sees that the expected value of a number chosen at random from the unit interval is equal to one-half, and for many people this assertion is perfectly reasonable. Still, one should note that the probability that X equals one-half is in fact equal to zero, so the probabilistic use of the word 'expected value' differs modestly from the day-to-day usage.

The probability distribution function and the expectation operation provide almost all of the language that is needed to describe the probability theory of an individual random variables. To be sure, there are several further notions of importance, but these may all be expressed in terms of the distribution or the expectation. For example, the most basic measure of dispersion for the random variable X is its 'variance,' which is defined in terms of the expectation by the formula

$$\mathrm{Var(X)} = \mathrm{E(X} - \mu)^2 \quad \text{where } \mu = \mathrm{E(X)}$$

Finally, the 'standard deviation' of X, which is defined to be the square root of Var(X), provides a useful measure of scale for problems involving X.

Introducing Independence

The world of probability theory does not stop with the description of a single random variable. In fact, it becomes rich and useful only when one considers collections of random variables – especially collections of 'independent' random variables.

Two events A and B in $\mathscr{F}$ are said to be independent provided that they satisfy the identity,

$$P(A \cap B) = P(A)\,P(B)$$

What one hopes to capture with this definition is the notion that the occurrence of A has no influence on the occurrence of B – and vice versa. Nevertheless, the quantities that appear in the defining formula of independence are purely mathematical constructs, and any proof of independence ultimately boils down to the proof of the defining identity in a concrete model $(\Omega, \mathscr{F}, P)$.

Consider, for example, the experiment of rolling two fair dice, one red and one blue. The sample space Ω for this experiment may be taken to be the 36 pairs (j, k) with $1 \le j \le 6$ and $1 \le k \le 6$, where one thinks of j and k as the number rolled on the red and blue die, respectively. Here, for any $A \subset \Omega$ one can set $P(A) = |A|/|\Omega|$ in order to obtain a model for a pair of fair dice. Under this probability model, there are many pairs of events that one can prove to be independent. In particular, one can prove that the event of rolling an even number on the blue die is independent of rolling an odd number on the red die. More instructively, one can also prove that the event of rolling an even number on the blue die is independent of the parity of the sum of the two dice.

Extending Independence

The concept of independence can be extended to random variables by defining X and Y to be independent provided that the events $\{X \le s\}$ and $\{Y \le t\}$ are independent for all real s and t. One easy consequence of this definition is that for any pair of monotone functions ϕ and ψ the random variables $\phi(X)$ and $\psi(Y)$ are independent whenever X and Y are independent. This mapping property reconciles nicely with the intuitive assertion: if X and Y have no influence on each other, then neither should $\phi(X)$ and $\psi(Y)$ have any influence on each other.

The importance of independence for probability theory will be underscored by the theorems of Section The Law of Large Numbers, but first the notion of independence must be extended to cover more than just pairs of random variables. For a finite collection of n random variables $X_1, X_2, \ldots, X_n$, the condition for 'independence' is simply that

$$\begin{aligned} &P(X_1 \le t_1, X_2 \le t_2, \ldots, X_n \le t_n) \\ &= P(X_1 \le t_1)P(X_2 \le t_2)\cdots P(X_n \le t_n) \end{aligned}$$

for all real values $t_1, t_2, \ldots, t_n$. Finally, an infinite collection of random variables $\{X_s : s \in S\}$ is said to be independent provided that every finite subset of the collection is independent.

The Law of Large Numbers

Any mathematical theory that hopes to reflect real-world random phenomena must provide some rigorous interpretation of the intuitive 'law of averages.' Kolmogorov's theory provides many such results, the most important of which is given in the following theorem.

Theorem 1 (*Law of Large Numbers*). Suppose that $\{X_i : 1 \le i < \infty\}$ is a sequence of independent random variables with a common distribution function $\mathscr{F}(\cdot)$, so $P(X_i \le t) = \mathscr{F}(t)$ for all $1 \le i < \infty$ and all real t. If the expectation $\mu = E(X_1)$ is well-defined and finite, then the random variables

$$\frac{1}{n}\{X_1 + X_2 + \cdots + X_n\}$$

converge to their common mean μ with probability one. More precisely, if one lets

$$A = \left\{\omega : \lim_{n\to\infty} \frac{1}{n}\{X_1(\omega) + X_2(\omega) + \cdots + X_n(\omega)\} = \mu\right\}$$

then the event A satisfies $P(A) = 1$.

The Central Limit Theorem

The second great theorem of probability theory is the famous Central Limit Theorem. Although it is not tied as tightly to the meaning of probability as the Law of Large Numbers, the Central Limit Theorem is key to many of the practical applications of probability theory. In particular, it often provides a theoretical interpretation for the 'bell curve' that emerges in countless empirical investigations.

Theorem 2 (*Central Limit Theorem*). Suppose that $\{X_i{:}1 \le i < \infty\}$ is a sequence of independent random variables with a common distribution function $\mathscr{F}$. If these random variables have a finite variance $\mathrm{Var}(X_i) = \sigma^2$, then

$$\lim_{n\to\infty} P\left(\frac{1}{\sigma\sqrt{n}}\{X_1 + X_2 + \cdots + X_n - n\mu\} \le x\right) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-u^2/2}\,\mathrm{d}u$$

Stochastic Processes

The most fundamental results of probability theory address the behavior of sums of independent random variables, but many applications of probability theory lead to sequences of random variables $\{X_n{:}1 \le n < \infty\}$ that may not be independent. Such sequences are called 'stochastic processes,' and they are of many different types.

The simplest nontrivial stochastic process is the 'Markov chain,' which is used to model random phenomena where X_{n+1} depends on X_n, but, given X_n, the value of X_{n+1} does not depend on the rest of the past $X_{n-1}, X_{n-2}, \ldots, X_1$. To construct such a process, one most often begins with an $n \times n$ matrix $T = \{p_{ij}\}$ with entries that satisfy $0 \le p_{ij} \le 1$ and with row sums that satisfy $p_{i1} + p_{i2} + \cdots + p_{in} = 1$. One then generates the Markov chain by making sequential selections from the set $\mathscr{S} = \{1, 2, \ldots, n\}$ in accordance with the rows of the 'transition matrix' T. Specifically, if $X_n = i$, then X_{n+1} is obtained by choosing an element of $\mathscr{S}$ in accordance with the probabilities (p_{ij}) given by the ith row of T.

A second group of stochastic processes that is of considerable practical importance is the set of 'martingales.' Roughly speaking, these are stochastic process that have the property that the expectation of X_{n+1} given the values of $X_n, X_{n-1}, \ldots, X_1$ is just equal to X_n. One reason that martingales are important is that they provide a model for the fortune of an individual who gambles on a fair game. Such gambling games are relatively unimportant in themselves, but many economic and financial questions can be reframed as such games. As a consequence, the theory of martingales has become an essential tool in the pricing of stock options and other derivative securities.

The theory of stochastic processes is not confined to just those sequences $\{X_n{:}1 \le n < \infty\}$ with the discrete index set $\{1 \le n < \infty\}$ and, in fact, almost any set $\mathscr{S}$ can serve as the index set. When one takes $\mathscr{S}$ to be the set of non-negative real numbers, the index is often interpreted as time, and in this case one speaks of continuous time stochastic processes. The most important of these are the 'Poisson process' and 'Brownian motion.' Brownian motion is arguably the most important stochastic process.

Directions for Further Reading

For a generation, Feller (1968) has served as an inspiring introduction to probability theory. The text only assumes a modest background in calculus and linear algebra, yet it goes quite far. The text of Dudley (1989) is addressed to more mathematically sophisticated readers, but it contains much material that is accessible to readers at all levels. In particular, Dudley (1989) contains many informative historical notes with careful references to the original sources.

For an introduction to the theory of stochastic processes, the text by Çinlar (1975) is recommended, and for an easy introduction to Brownian motion, martingales, and their applications in finance, one can consult Steele (2000).

For background on the early development of probability theory, the books of David (1962) and Stigler (1986) are useful, and the article by Doob (1994) helps make the link to the twenty-first century. Finally, for direct contact with the master, anyone does well to read Kolmogorov (1933).

Abstract

This article is divided into two sections. The first reviews the formal theories of quantitative and qualitative probability. Conditions are given when a quantitative probability exists that agrees with (or almost agrees with) a qualitative probability. The second section reviews four kinds of semantics for the quantitative theory: the Subjective, the Classical (or Logical), the Objective, and the Fisher–Kyburg interpretation. The Subjective interpretation is presented through deFinetti's Dutch Book argument. Variants of Logical interpretations are described as these relate to LaPlace's *Principle of Insufficient Reason*. Two varieties of Objective probability are considered: limiting frequency theory and chance (or propensity) theory. Last, the Fisher–Kyburg theory is sketched in relation to fiducial probability.

Qualitative and Quantitative Probability

Introduction

It is entirely unremarkable that the commonplace word 'probability' and its cognates display a wide variety of distinct meanings in ordinary language. It is used as a classificatory concept, as in "It is *probable that* it will snow this winter" or "It is *improbable that* a fair coin will land heads 10 times in succession." It is used as a (qualitative) comparative relation, as in "It is *more probable that* someone will be killed by lightning *than* by a falling meteorite next year." And, of course, it is used as a quantitative concept throughout science, e.g., Mendel's law, "The probability is 0.75 that the offspring of a cross between simple hybrids will show the dominant trait." What is worth noting, however, is that despite longstanding controversies over the legitimate interpretation of 'probability,' these diverse usages can nonetheless be linked easily to a few formal theories of mathematical probability.

The received formal theory of quantitative probability, due to Kolmogorov, is elegant. Mathematical probability is a (real-valued) function, $\boldsymbol{P}$, with values between 0 and 1 (inclusive), defined over a field of events closed under the Boolean operations of union, intersection, and complementation. The sure event Ω is certain, $\boldsymbol{P}(\Omega) = 1$, and $\boldsymbol{P}$ is additive over unions of disjoint events. The qualitative formal theory of probability uses a binary relation $\langle$ also defined on an algebra of events: $E \langle F$ means that event F is more probable than event E. The qualitative formal theory is presented through axioms that mimic the quantitative one.

The outline for this article is as follows. Sections The Formal Theory of Quantitative Probability and The Formal Theory of Qualitative Probability review relevant details of the received, formal (mathematical) theories of quantitative and qualitative probability, and some basic connections between them. (This section includes some technical results that the reader might bypass initially, to return to on a second reading.) Section Interpretations of Quantitative Probability surveys several interpretations of the quantitative theory, including Sections Subjective Probability, Logical (or Classical) Probability, Objective Probability, and an approach (Section The Fisher–Kyburg Interpretation) relating to Fisher's enigmatic fiducial probability. Additional readings are suggested in Section Additional Readings.

The Formal Theory of Quantitative Probability

Begin with Kolmogorov's (1956) mathematical theory for quantitative probability, dating from the 1930s. A measure space $\langle \Omega, \mathscr{F}, \boldsymbol{P} \rangle$ is triple comprised by:

1. a set of possibilities, Ω, whose elements, ω, are points of the space. A field $\mathscr{F} = \{E \text{ of subsets of } \Omega\}$. Elements of $\mathscr{F}$ are the events of the space. It is assumed that $\Omega \in \mathscr{F}$. Being a field, $\mathscr{F}$ is closed under finite unions, intersections, and complementation with respect to Ω. When $\mathscr{F}$ is infinite, usually it is required
2. that $\mathscr{F}$ is a σ-field, closed under countable unions and intersections.
3. A probability function $\boldsymbol{P}$ over $\mathscr{F}$ satisfying these axioms:
   3.1. $0 \leq \boldsymbol{P}(E) \leq 1$
   3.2. $\boldsymbol{P}(\Omega) = 1$
   3.3. $\boldsymbol{P}(E \cup \mathrm{F}) = \boldsymbol{P}(\mathrm{E}) + \boldsymbol{P}(\mathrm{F})$, whenever $\mathrm{E} \cap \mathrm{F} = \varnothing$. (finite additivity)
   3.4. $\boldsymbol{P}(\cup E_i) = \Sigma_i \boldsymbol{P}(E_i)$, whenever $E_i \cap E_j = \mathrm{F}\,\varnothing$ for $i \neq j$ (σ-additivity).

Moreover, when $\boldsymbol{P}(F) > 0$, a conditional probability given F, $\boldsymbol{P}(\cdot|F)$, is well defined over $\mathscr{F}$ by the equation

4. $\boldsymbol{P}(\cdot|F)\boldsymbol{P}(F) = \boldsymbol{P}(\cdot \cap F)$

Kolmogorov's mathematical theory provides a basis for each of the two nonquantitative uses of probability, illustrated above.

The classificatory concept of probability may be explicated as:

'E is *probable*' provided that $\boldsymbol{P}(E) > c > 0.5$, for some value c, determined by the context of the assertion. Then, 'E is *improbable*' means that the complementary event E^c is probable.

The (qualitative) comparative concept of probability may be explicated as:

'E is *more probable than* F' provided that
$$\boldsymbol{P}(E) > \boldsymbol{P}(F).$$

The Formal Theory of Qualitative Probability

A mathematical theory of qualitative probability is readily obtained from the quantitative one. The binary relation $\langle$ over events is said to be a (qualitative) comparative probability relation if it satisfies the following three axioms that parallel the first three axioms of Kolmogorov's theory.

5.1. $\langle$ is an acyclic, transitive relation over $\mathscr{F}$. That is, if $E \langle F$ and $F \langle G$ then $E \langle G$, and it is never the case that $E \langle E$. The qualitative relation that E and F are equiprobable events, denoted $E \approx F$, is defined by the condition that neither $E \langle F$ nor or $F \langle E$. Then $\approx$ is transitive and reflexive, i.e., $E \approx E$ always obtains.
5.2. $\varnothing \langle \Omega$ and for no event E, $E \langle \varnothing$.
5.3. Provided that $E \cap (F \cup G) = \varnothing$, $F \langle G$ if and only if $(E \cup F) \langle (E \cup G)$.

Say that a quantitative probability $\boldsymbol{P}$ agrees with the comparative probability relation $\langle$ on the condition that, $\boldsymbol{P}(E) < \boldsymbol{P}(F)$ if and only if $E \langle$ F. deFinetti (1931) asked whether every comparative probability relation $\langle$ has an agreeing quantitative probability. Kraft et al. (1959) established that the answer is no, even when $\mathscr{F}$ is a finite space. However, they also showed that for finite spaces, the following (stronger) additivity condition is both necessary and sufficient for an agreeing quantitative probability to exist.

5.4. Let $(E_1, \ldots, E_m)$ and $(F_1, \ldots, F_m)$ be two sequences of events from $\mathscr{F}$ such that, for each point ω in Ω, the same number of events from each sequence contain ω. If it is not the case that $F_i \langle E_i$ $(i = 1, \ldots, m-1)$, then it is not the case that $E_m \langle F_m$.

Aside: It is interesting to note that the very same condition, expressed for a quantitative probability, serves as a necessary and sufficient condition for extending the domain of a quantitative probability, Horn and Tarski (1948).

A different relationship between quantitative and qualitative probabilities is also worth consideration. Say that a quantitative probability $\boldsymbol{P}$ almost agrees with the comparative probability relation $\langle$ on the condition that $\boldsymbol{P}(E) < \boldsymbol{P}(F)$ only if $E \langle F$. That is, quantitative strict inequalities entail the corresponding qualitative (strict) inequality. However, when $\boldsymbol{P}$ almost agrees with $\langle$, it may be that $\boldsymbol{P}(E) = \boldsymbol{P}(F)$ and $E \langle F$. Kraft et al. (1959) provide an example of a finite space equipped with a qualitative probability relation that admits a continuum of almost agreeing quantitative probabilities but no agreeing quantitative probability. For finite spaces, the analog to (5.4) is the following necessary and sufficient condition for a qualitative probability to admit an almost agreeing quantitative probability.

5.5. Let $(E_1, \ldots, E_m)$ and $(F_1, \ldots, F_m)$ be two sequences of events from such that, for each point ω in Ω, fewer events from the first sequence contain ω than do events from the second sequence. If it is not the case that $F_i \langle E_i$ $(i = 1, \ldots, m-1)$, then $E_m \langle F_m$.

On infinite spaces, the situation is more complex and more interesting. The following illustrates how a qualitative probability may make finer discriminations than any quantitative probability, i.e., the qualitative relation $\langle$ is non-Archimedean.

Example

Let $\mathscr{F}$ be the set of all subsets of the positive integers $\{1, 2, \ldots\} = \Omega$. Let $\langle$ be a qualitative probability subject to the following two constraints:

1. Each integer, i.e., each point is as probable as any other. That is, for each pair of integers i and j, $i \approx j$.
2. The qualitative probability relation respects proper subsets. That is, whenever $E \subset F$ (but $E \neq F$) then $E \langle F$.

(*Aside*: To establish the existence of a qualitative probability satisfying these constraints requires an appeal to the Axiom of Choice.) Condition (1) ensures that no countably additive probability agrees with $\langle$, since any agreeing probability must assign each point of Ω probability 0. Condition (2) insures that no finitely additive probability agrees with $\langle$, because, by the fact just noted, $\boldsymbol{P}\{i, j\} = \boldsymbol{P}\{i\} + \boldsymbol{P}\{j\} = 0$. But by (2) $\{i\} < \{i, j\}$. There exists an almost agreeing (uniform) finitely additive probability for $\langle$, where $\boldsymbol{P}\{i\} = 0$ for each integer i. Hence, this qualitative probability ordering is finer than any quantitative probability can be.

Interpretations of Quantitative Probability

Subjective Probability

The contemporary theory of subjective (or personal) probability has its roots in the writings by Ramsey (1926) and deFinetti (1937), from the 1920s and 1930s. Savage (1954) gives what to many is a definitive account of this line of reasoning. The subjective interpretation of the mathematical theory treats probability as a (rational) agent's assessment of uncertainty about a truth-value bearing proposition, E. (Here, equate the proposition asserting E and the event E of the mathematical theory.) The agent's uncertainty about E is expressed as her/his degree of belief in E, and under appropriate assumptions may be measured by the agent's disposition to wager-on-E (*see* Bayesian Statistics).

The so-called 'Dutch Book' argument offers a prudential account of why the rational agent who is willing to engage in betting (under conditions made explicit, below) will have degrees of belief that conform to the formal probability calculus. Suppose that betting is in monetary units.

Definitions

A bet on E, at odds of $r{:}(1-r)$, with total stake $S > 0$ pays off to the agent with a gain of $(1-r)S$ in case E obtains, and with a loss of $-r(S)$ in case E fails to obtain.

A bet against E, at odds of $r{:}(1-r)$, with total stake $S > 0$ pays off to the agent with a loss of $-(1-r)S$ in case E obtains, and with a gain of $r(S)$ in case E fails to obtain.

The agent's betting odds of $r{:}(1-r)$ for E are fair just in case the agent is indifferent between betting on and betting against E at those odds, at least for moderate size stakes.

A (finite) set of bets constitutes a Dutch Book against the agent if the agent suffers a net loss from these bets regardless which state of affairs obtains.

The agent's fair betting odds are coherent if no Dutch Book is possible against them.

An elementary version of the 'Book' argument is captured in the following result:

The Dutch Book Theorem (deFinetti and Ramsey)

Suppose that the rational agent offers fair odds for each event E in the space $\mathscr{F}$ and for moderate size stakes is willing to accept finite combinations of bets made at her/his fair odds. Then the agent is coherent, that is, immune to having a Dutch Book made if and only if her/his fair odds satisfy the axioms of mathematical (finitely additive) probability (3.1)–(3.3).

Conditional probability, too, can be made the subject of the Dutch Book criterion by introducing called-off bets, e.g., a bet on E given F, which is annulled if F fails to occur.

Definition

A called-off bet on E given F, at odds of $r{:}(1-r)$, with total stake $S > 0$ pays off to the agent with a gain of $(1-r)S$ in case $E \cap F$ obtains, pays off with a loss of $-r(S)$ in case F obtains but E fails to obtain, and results in no change (0 payoff) in case F fails to obtain.

The concept of a called-off bet against E given F is likewise defined in parallel with the respective concepts for betting against an event, as is the condition of fair called-off odds. When called-off bets are included among those to be wagered on, the following improved result ensues.

Dutch Book Theorem for Conditional Probability

Assume that the agent offers fair odds and fair called-off odds, and for moderate size stakes is willing to accept finite combinations of wagers at these fair odds. Then the agent is coherent if and only if the fair odds satisfy the axioms of mathematical (finitely additive) probability (3.1)–(3.3), and the definition of conditional probability (4).

- *Remark*: The reader is alerted to the sad fact that when $\boldsymbol{P}(F) = 0$, condition (4) does not establish that $\boldsymbol{P}(\cdot|F)$ is a probability over $\mathscr{F}$, i.e., it may fail axioms (3.1)–(3.3). Hence, the Dutch Book argument for conditional probability does *not* establish that, given an event F of probability 0, the coherent agent's called-off fair odds given F constitute a probability.
- *Remark*: Some writers use a dynamic interpretation of the conditional probability, so that $\boldsymbol{P}(\cdot|F)$ designates the agents' subsequent degrees of belief upon learning that event F obtains. The Dutch Book argument for conditional probability does not underwrite this dynamic interpretation. It is part of the static constraints on a rational agent's degrees of belief at a fixed time. The called-off bets may, however, serve as a model of the agent's hypothetical reasoning at the fixed time.

Shimony (1955) introduces a more restrictive standard of coherence, which he calls strict coherence. An agent's fair odds are strictly coherent provided that there is no possibility of making a 'book' against her/him where the agent stands no chance of winning on net, but risks losing for at least one point of Ω.

Shimony establishes that an agent's fair odds are strictly coherent if and only if they are coherent and only the impossible event $\varnothing$ receives probability 0. Despite the desirability of having one's odds be strictly coherent, the resulting standard precludes continuous probability distributions, unfortunately.

Savage (1954) gives an elegant version of personal probability in which the agent's probability is reduced to her/his rational preference over acts. In the briefest outline, Savage's axioms include the assumption that the agent's preferences reveal a qualitative probability, as follows. Let b and w be prizes and assume that the agent prefers receiving the better prize b to the worse one w. For an event E, let the *wager-on-E* be the act that rewards the agent with prize b if E occurs and with w if E fails. Thus, these wagers are generalization of the bets used in deFinetti's Dutch Book argument. Savage postulates that the agent strictly prefers the wager-on-F to the wager-on-E if and only if the qualitative probability relation $E \langle \mathrm{F}$ obtains. Savage introduces additional postulates to insure that exactly one (finitely additive) quantitative probability agrees with this qualitative probability. That quantitative probability is offered as the agent's personal probability over events.

Logical (or Classical) Probability

Dating to Laplace's (1951) eighteenth-century work, at least, is the view that quantitative probability is determined once the space $\langle \Omega, \mathscr{F} \rangle$ is fixed. In its simplest version, LaPlace's *Principle of Insufficient Reason* states that the points of Ω determine equiprobable states. However, this principle leads quickly to a variety of inconsistencies, which are worth noting.

For one, LaPlace's principle makes the probability of an event depend upon which partition of states is used to describe it. A die's landing with the 1-spot up is made equiprobable with its not landing that way when Ω is just the binary partition; in which case, by LaPlace's principle, the probability is 1/2 for each outcome. However, if the state space is partitioned into six points depending upon how many spots land facing upwards, LaPlace's principle yields a probability of 1/6 for the outcome with 1-spot showing uppermost. We may continue to refine the state space, to include the information that the sum of the visible side faces on the die (as seen from a given perspective) is either less than, or is equal to, or is greater than the face showing uppermost. Then there are 14 distinct possibilities, but only one of these has a 1-spot uppermost. Then, by LaPlace's principle, the probability of a 1-spot uppermost is 1/14.

When the state space is continuous, the problem of applying LaPlace's principle grows more serious as a transformation to an equivalent random variable may lead to a different probability. For example, if Ω is the set of real numbers in the unit interval [0,1] and $\mathscr{F}$ is the space of Borel measurable subsets of the identity variable $X(\omega) = \omega$, then LaPlace's principle yields a uniform distribution over X. However, if we transform the space so that $\Omega' = [0, 1]$ with $\omega' = \omega^3$ and define the equivalent random variable $Y(\omega') = \omega'$, then Laplace's principle yields a uniform distribution when applied to the equivalent random variable Y. But a uniform probability distribution over X is evidently inconsistent with a uniform probability distribution over Y.

In an early-twentieth-century variant of LaPlace's idea, Keynes (1921) strove to revitalize the principle by applying it to

a formalized language in the fashion of Russell and Whitehead's *Principia Mathematica*. Moreover, Keynes's theory has the added subtlety that takes qualitative probability as primitive, and that relation is only partially defined: Not all propositions can be compared even by a qualitative probability relation in Keynes's system. Following Keynes, Carnap (1950) developed quantitative probability for a logical calculus. At first, Carnap sought to determine a single, well-defined quantitative probability for the monadic predicate calculus. But soon enough his approach, Carnap and Jeffrey (1971), became one best described as subjectivist, favoring symmetry conditions for atomic propositions similar to deFinetti's concept of exchangeability. Papers by Scott and Krauss (1966) and Gaifman and Snir (1982) continue this tradition.

A more productive alternative than appeal to a formalized language to revive LaPlace's principle is the use of mathematical symmetries as a basis for fixing the necessary equiprobable states. Most notable is Jeffreys's (1961) theory of *Invariance*, dating from the 1930s. Jeffreys's sophisticated Bayesian treatment appeals to transformational invariants of parametric statistical models of the observed data to determine a 'prior' probability for the parameter. For example, a uniform 'prior' probability is the invariant distribution for a location parameter, e.g., for the mean n of data from a normal $\mathbf{N}[\mu, 1]$ distribution. Fraser (1968) uses mathematical groups to determine the necessary invariances for fixing a probability, e.g., Haar measure. Each of these theories provides a *local*, not a *global*, interpretation of probability. That is, these theories provide necessary conditions for probability defined with respect to a specific inference problem. When multiple inference problems are considered at once, e.g., when the same theoretical quantity is a location parameter for one data set and a scale parameter for a second data set, difficulties ensue. These theories then generate what must be seen as either inconsistent or nonunique solutions. Furthermore, the invariant probabilities are not always countably additive. So called 'improper' priors, e.g., a uniform distribution over a real-valued parameter, correspond to a purely finitely additive probability by assigning equal probability to each unit interval for the parameter, which intervals constitute the elements of a countable partition. Dawid et al. (1973) provide an important litany of 'paradoxes' for these theories, involving both transformations of parameters and multiple, simultaneous inferences.

Yet another approach for reviving LaPlace's principle is found in the original work of E.T. Jaynes (1983), who uses entropy as a guide to uncertainty. His principle of *Maximum Entropy* dictates that, subject to a set of constraints (i.e., expectations for bounded random variables), a rational agent should fix probability over the space by choosing that probability that simultaneously satisfies the constraints while maximizing entropy. (For discrete spaces this requires choosing the probability $\boldsymbol{P} = \{p_i{:}i = 1, \ldots\}$ to maximize $-\sum_i \log(p_i)\ p_i$ subject to the constraints.) For example, when Ω is finite and the constraint set is vacuous, the uniform distribution over Ω maximizes entropy. Unfortunately, the Maximum Entropy principle inherits the problems of LaPlace's principle, as it is sensitive both to repartitioning the space Ω and, in the continuous case, equivalent transformations.

Objective Probability

Limiting and Finite Frequency Interpretations

Since Venn's (1876) writings in the nineteenth century, at least, it has been popular to attempt to link probability with limiting frequency in infinite sequences of repeated trials, thereby underwriting an objective interpretation. von Mises' (1931, 1939) work in the early twentieth century offered a mathematical program for this approach. For von Mises, probability applies to a collective, which is a suitably random sequence of repeated trials. For example, a (hypothetically infinite) sequence of repeated flips with a particular coin that can land either only heads-up or tails-up forms a collective and supports the fact that the objective probability of heads up is 1/2 provided that:

1. the limiting frequency in the sequence of the outcome heads up is 1/2.
2. the sequence of outcomes is random, i.e., this limiting frequency for heads up is invariant over selections of infinite subsequences.

Several important mathematical problems attend this approach. As is well known, the set of events that have a limiting frequency in a given sequence may fail to form a field (let alone a σ-field). Moreover, when Ω is infinite, even when limiting frequencies do exist they may fail to be σ-additive. However, the formal aspect of von Mises' program that has been given most scrutiny is the theory of randomness.

Evidently, for a sequence to pass muster as random in von Mises's sense, not all infinite subsequences are relevant. That is, assuming the limiting frequencies of the binary events {heads up, tails up} exist and are not either 0 or 1, trivially, there will be, e.g., the infinite subsequence consisting of outcomes with only heads up, whose limiting frequency for that event is 1, not 1/2. To sidestep this reduction of the randomness concept, von Mises proposed that only certain families of subsequences are relevant to objective randomness. These subsequences are determined by combinations of place selection rules, e.g., choose every kth trial, and tests for after-effects, e.g., consider the subsequence of outcomes preceded by two-consecutive 'heads up' outcomes. One intuition von Mises offered for these restrictions is that the random sequence should be shown to be immune to sure profits from any feasible gambling system that might be used against it. Wald (1937) showed that a formally consistent theory was possible if the tests for randomness were limited to a countable infinity of rules. Church (1940) suggested using the denumerable class of recursive functions, in an attempt to make the concept of a random sequence language invariant. However, Ville (1939) showed that collectives based on denumerably many selection rules fail to validate some of the basic 'strong law' theorems of Kolmogorov's theory, e.g., the law of the iterated logarithm fails. Also, by appeal to martingale theory, Ville showed that such collectives fail von Mises's intuitive criterion for randomness: they do not preclude successful gambling systems.

Reichenbach (1938, 1949) proposed a rival frequency theory that avoided von Mises's randomness conditions, even permitting its application to finite sequences. In doing so, however, the resulting theory depends ever more heavily on epistemic considerations for its warranted application. For example, a (sequence) that alternates successively between

heads up on odd numbered flips and tails up on even numbered flips has a limiting frequency of 1/2 for each outcome. But, given that fact about the order of outcomes, we would be hard pressed to find a good use for this 'objective' probability when making inferences about such a process.

A more interesting finite-frequency interpretation is based on Kolmogorov's (1963, 1968, 1984) idea for interpreting randomness as informational complexity in finite sequences. A proper account of this approach is beyond the scope of this article. For first-rate discussions, see Fine (1973) and van Lambalgen (1987).

Chance and Propensity Interpretation

The philosophers Braithwaite (1953), Hacking (1965) and Levi (1980) propose and defend an objective interpretation of probability based on the idea that an objective chance is a theoretical, quantitative disposition for a process or kind of trial to respond when activated. That is, consider a process or kind of trial described as flipping this coin by hand. The chance of its landing heads up on such a process is taken to be an unobserved, quantitative disposition for the coin to respond when flipped. The propensity interpretation is thin, on purpose, in that chances satisfy the mathematical theory of probability by stipulation!

What is particularly novel in these approaches about making chance a theoretical concept is that probability is *not* reduced to observed frequencies, contrary to the frequency interpretation. Rather, the meaning of the theoretical term *chance* is given by rules for testing chance claims (Braithwaite) or by rules linking chance with subjective probability (Hacking and Levi). In the latter case, central to the meaning of chance is a so-called *Direct Inference* principle. Put simply, that principle asserts: the personal probability $\boldsymbol{P}$ for a specific outcome O of the kind of the trail occurring is p, given the information that the chance is p for outcome O on that kind of trial. To wit: $\boldsymbol{P}$ (coin lands heads up on a toss | chance is p that the coin lands heads up on a toss) $= p$.

This treatment of chance as a theoretical term, with it meaning supplied by rules for application of the concept, accords with the Pragmatic turn in philosophy as proposed by Peirce (1932) in the nineteenth century, though Peirce himself favored a frequency interpretation.

The Fisher–Kyburg Interpretation

Fisher (1956) and Kyburg (1961) introduce an original semantics for probability, focused on the single-case assertion, e.g., (*). The probability is 1/2 that the next flip of this coin lands heads up.

For this theory, probability is fundamentally epistemological, grounded on both knowledge and ignorance of class-frequencies. The statistician who asserts (*) is required to have:

1. *knowledge* of frequencies of outcomes of heads in the population of flips with this coin, a population that includes the next flip.
2. *ignorance* of the statistics of outcomes in a smaller statistical population of coin flips that includes the next flip.

In this sense, their theory takes instances of direct inference (based on frequency information about populations) as the definition of probability.

For both Fisher and Kyburg, this interpretation of probability underwrites an important statistical analysis, e.g., Fisher's fiducial probability. For example, let the random variable X take values from a population with known frequencies approximated by a normal distribution, $\mathbf{N}(\mu, 1)$, but with parameter μ unknown. Then the pivotal quantity $V = (\mu - X)$ has a known distribution in this population. Its values are distributed according to a normal $\mathbf{N}(0, 1)$ distribution. Suppose $X = 7$ is observed on a particular trial. The Fisher–Kyburg theory then asserts that on this same trial, given $X = 7$, the statistician's probability distribution for V is $\mathbf{N}(0, 1)$. This claim rests on the assertion of ignorance on the part of the statistician: the statistician knows of no smaller population that includes this trial with statistics for V different from those of the $\mathbf{N}(0, 1)$ population. The upshot is a fiducial $\mathbf{N}(7, 1)$ probability distribution for μ, given $X = 7$. When a random variable X has a continuous, parametric distribution $F(X, \theta)$, then F itself may be treated as the pivotal quantity, having a known uniform U[0, 1] distribution. Fiducial inference about F, given the observation that $X = x$, yields probability for the unknown parameter satisfying Fisher's enigmatic formula: $P(\theta|X) = -\partial F/\partial\theta|_{X=x}$. Kyburg's theory has the added generality over Fisher's in that he uses interval-valued frequency information, leading to a theory with lower and upper probability for single-case assertions. Despite the considerable novelty of this approach, it is challenged severely by nuisance parameters. That is, this interpretation of probability provides only a limited account of marginal probability, as its theory of conditional probability is not well defined, at least not as required by Bayes's theorem.

Additional Readings

Nagel's et al. (1936) and Nagel (1939) essays on quantitative probability are excellent reviews, still, of philosophical issues relating to rival interpretations. In particular, one important issue not addressed here is whether objective probability requires a commitment to indeterminism in science. Nagel makes clear why there is no conflict between objective probability and deterministic laws in science. A more elementary presentation of rival interpretations of quantitative probability is found in Kyburg's (1970) textbook.

Fine's (1973) book gives a good overview of complexity theories and randomness, relating in particular to Kolmogorov's theory from the 1960s.

Fishburn's (1986) article offers a wealth of insights on both philosophical and formal questions relating to qualitative and quantitative concepts of probability. The bibliography there is particularly noteworthy. Also valuable is the discussion of comparative probability given in Walley and Fine (1979).

Probation, Offenders and Risk

Peter Raynor, Swansea University, Swansea, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews the history and development of probation services and their gradual evolution from a focus on the welfare of offenders to a focus on risk, public safety, and the reduction of reoffending. Probation in England and Wales is presented as a particularly clear example of how probation has had to adapt to both new research findings and political fashions. The conflict between these different influences is explored, and possible scenarios for future development are discussed.

Introduction: Origins and Principles

This article describes the origins of probation and distinctive features that have traditionally characterized its theory and practice, the threats and challenges posed by evaluation research, the revival of rehabilitation in the 1990s as an evidence-based approach to managing and reducing the risk of offending, and contemporary developments that point to new challenges and possible threats. At each stage in this story, probation has been shaped by its social and political environment as well as its own professional traditions, and some environments have been more favorable than others.

The origins of probation are complex. Recent historical research points to several sources. In the United Kingdom, the Police Court Mission of the Church of England Temperance Society traced its origin to a donation by the shoemaker Frederick Rainer in 1876. Other obvious precursors can be found in the mid-nineteenth century voluntary work of John Augustus in Boston, Massachusetts (US), who befriended and helped offenders placed under his supervision by the Courts. At the same time, the innovations of Matthew Davenport Hill, Recorder in Birmingham, England, released selected offenders on recognizance when suitable volunteer supervisors could be found in the community. The first legal enactment of a recognizable form of probation was in Massachusetts in the United States in 1873. England and Wales persisted with a fully voluntary system until early in the next century, when a Probation of Offenders Act was passed in 1907. (England and Wales will be mentioned together in this article, because for criminal justice purposes, these two countries within Britain form a single jurisdiction. Scotland has a separate legal system and its own arrangements.) Vanstone (2008) dates the major period of international expansion as lasting from 1878 to 1920 and lists 43 jurisdictions to which probation spread between those dates. There was variation: the administering agency could be judicial or could be part of central or local government; punishment could be conditionally withheld or imposed and then suspended subject to compliance with supervision; sometimes probation would be an alternative to prosecution rather than a sentencing option, and supervision was not always a requirement. However, the 'Anglo-American model' (Vanstone, 2008) was widely adopted, with probation used instead of punishment, supervision by an officer of the Court, and the option of returning to Court for reconsideration of sentence if the requirements of probation were breached. These requirements normally included reporting to a supervising officer when required, receiving visits at home, 'leading an industrious life,' and avoiding further offenses. In the earlier decades of the twentieth century, probationers could be required to abstain from alcohol.

The roots of probation can be found in a mixture of religious missionary commitment and nineteenth century charitable endeavor, showing concern for the welfare of poor people and a desire to improve their morals and behavior, particularly where drink was concerned. Fuller accounts of the history are available in Vanstone (2004), Raynor and Robinson (2009), and, for recent periods, Canton (2011). By the early twentieth century, most industrial countries were responding to demands that the state should play a greater role in safeguarding the welfare of citizens, and activities such as social work and probation were drawn into this process. For example, the 1907 British Probation of Offenders Act was part of a period of Government-led social reform that laid the foundations for the later welfare state (Vanstone, 2004). Consequently, during the first half of the twentieth century, probation in many countries moved from the periphery of charitable and religious endeavor to become a small but important part of the system of state-funded welfare services and an integral part of the criminal justice system. By the early 1950s, the criminologist Max Grünhut, a refugee from Nazi Germany who established the study of criminology at Oxford University, reflected a professional consensus when he described the essential features of probation as "a combination of two things, conditional suspension of punishment, and personal care and supervision by a court welfare officer" (Grünhut, 1952: p. 168).

By this time, professional thinking and literature were emphasizing the process of individual supervision and importance of the supervisory relationship. Offenders under supervision would report to probation offices, often weekly, for regular interviews with their probation officer. Originally influenced by what would now be considered a strange mixture of ideas about the psychology of offending, including Lombrosian theories and an early interest in eugenics (Vanstone, 2004), probation officers and people who ran their training courses increasingly adopted many ideas from psychodynamic casework, which had been enthusiastically embraced by the social work profession. Many probation officers trained on social work courses and saw themselves as

social workers, albeit with a special role and expertise in the criminal justice system and the Courts.

Two other early and durable developments in probation work are worth noting at this stage. The first concerns the provision of information and advice about individual defendants to sentencing judges or magistrates before sentence is passed. This was a development from the practice of early voluntary workers such as John Augustus and Police Court Missionaries who, if they had interviewed a defendant who they thought could be saved from imprisonment, would often directly address the Court to plead for release under supervision. Over the years, this became formalized as a written document, known as a Social Enquiry (or Inquiry) Report, and more recently a Pre-Sentence Report. Such reports have become a major part of the work of most probation services, and much has been written about their role and contents: for example, early controversies concerned whether reports should make an explicit recommendation as to sentence or simply provide a history and leave the sentencing decision to the Court; whether they should contain a full social history, as a social casework file might, or whether they should concentrate only on matters relevant to the current offense; whether they should be understood as a document supporting the defendant or as neutral professional advice; and whether they have any significant influence on sentencing decisions. Evidence from England and Wales suggests that they do, but only if carefully prepared and well written (Gelsthorpe and Raynor, 1995). Other issues raised from the 1980s onward concern the contribution of stereotyped language and thinking in presentence reports to sentencing outcomes that discriminate against women (see Dominelli, 1984; Eaton, 1986; Gelsthorpe, 1992; Hedderman and Gelsthorpe, 1997) and minority ethnic groups (Whitehouse, 1983; Moxon, 1988; Dominelli et al., 1995; Hudson and Bramhall, 2005), and how such outcomes might be avoided. Originally little more than a plea for mercy and an offer to supervise, presentence reports have become sophisticated documents informed by detailed risk assessments, often following a standard format, sometimes provided as a template on probation service computers.

The second early accretion to the probation officer's role in most countries was responsibility for the supervision of some offenders released from custodial sentences. Known in Britain as aftercare, and later as through-care or resettlement (or, in the United States, reintegration or reentry), this also has roots in nineteenth century charitable work. Voluntary organizations (for example, Discharged Prisoners' Aid Societies) formed to provide support and assistance on release to prisoners deemed as having paid their debt to society, or simply as unfortunate, and in need of help to reestablish themselves in the community. Religious groups organized Prison Gate Missions, and as in the Police Court Missions, encouraged abstention from alcohol. During the twentieth century, many custodial sentences included periods of supervision after release, with the possibility of recall to prison for failure to comply with license requirements. Increasingly, the supervision of offenders subject to such requirements came to be undertaken by probation service staff rather than by voluntary organizations. By the end of the 1960s, in England and Wales, a substantial part of the Probation Service's workload was made up of aftercare cases, mainly young offenders but including some older offenders on parole after early release from long sentences, and several thousand 'voluntary aftercare' cases where there was no requirement to supervise but a voluntary agreement to provide and receive advice and support. These voluntary cases had almost completely disappeared from the probation workload in England and Wales by the end of the twentieth century, but were an important part of the job in the 1960s and 1970s.

The statutory aftercare caseload, consisting of enforceable licenses, grew as prison populations rose and more categories of prisoners became subject to various forms of conditional supervised release. These developments emphasized the controlling side of the probation officer's work: released prisoners were supervised on behalf of the penal system rather than the Courts, and this helped to both integrate probation more closely into the structure of the criminal justice system and focus its work increasingly on adult offenders.

The Response to 'Nothing Works'

The era of comfortable identification with the social work profession, and confidence that good results were being achieved, came to an end in the mid-1970s, when a series of studies of the outcomes of rehabilitative work with offenders indicated that no sentence, including probation, was significantly affecting reoffending rates. The best known and most vivid expression of these conclusions was an American article by Robert Martinson that argued that there was "very little reason to hope that we have in fact found a sure way of reducing recidivism through rehabilitation" (Martinson, 1974: p. 49). This was summarized and simplified by the press as 'nothing works,' and similar studies were conducted in other countries and in relation to other aspects of social work. These studies often had sophisticated comparative designs, including random allocation to treatment and comparison groups, but their careful measurement of outcomes was not matched by a similar clarity over inputs. It was correctly argued, for example, by Fischer (1976), that such studies often failed to distinguish between good and bad practices, but simply documented the aggregate absence of effect that came from mixing the two together. However, research results that questioned the effectiveness of spending on welfare were popular with some politicians at a time when increasing welfare budgets in Western countries were coming under pressure, and in some countries 'nothing works' became an orthodoxy that went largely unchallenged for a decade (McGuire, 2002).

Probation's response to this kind of challenge can best be illustrated by examining what happened in England and Wales, which then had one of the oldest and most sophisticated Probation Services and could be regarded as a paradigm case of how probation reshapes itself in response to changing expectations and wider policies. Briefly, the apparent discrediting of the 'treatment model' led to new thinking about what probation could offer as a sentencing option within the criminal justice system. It was demonstrably much cheaper than prison, and if nothing works, cheaper is better. Probation's new goal became not so much to change offenders as to change the decisions made about them, by offering supervised alternatives to custodial sentences under various guises: 'diversion,'

'intermediate sanctions,' and various 'intensive probation' schemes designed to appear demanding enough to be a realistic sentence for offenders who would otherwise have gone to prison. Additionally, new community-based sentencing options appeared, including Community Service (later known as Community Punishment, then Unpaid Work, then Community Payback). This change of direction toward providing alternatives to custody was confirmed by the Home Office (which then directed criminal justice policy in England and Wales) in a 'Statement of National Objectives and Priorities' in 1984, and for nearly a decade, this strategy was relatively successful (Raynor and Robinson, 2009). Furthermore, this was paradoxically a creative period for practitioners interested in developing more effective ways of supervising offenders. Intensive forms of probation meant more time under supervision, which needed to be filled with meaningful content. Probation officers developed day centers, and many different forms of group work, sometimes involving structured programs and sometimes anticipating later developments by teaching social skills, self-management, and problem solving.

More fundamentally, 'alternatives to custody' could not compete seriously with prison unless they could be shown not to expose the public to significantly greater risks of victimization by offenders. Thus the ideas of public protection and risk management, which had previously been minor themes in probation practice, became more salient. At this early stage, little attempt was made to distinguish between the risk of reconviction and the risk of serious harm to victims; this distinction was to become increasingly important during the next few years. The probability of reconviction for people on probation in England and Wales is normally around 37% within a year of the start of the probation order, but the risk of serious harm is much lower and, being a relatively rare event, much harder to predict. Probation staff during the era of diversion had been used to estimate another kind of risk, namely, the risk of receiving a custodial sentence, and had been used to offer more intensive supervision when custody seemed likely, so the principle of offer more intervention when risk was higher was already known before the focus shifted from the offender's risk of a custodial sentence to the potential victim's risk of suffering harm. Once that shift was under way, the purpose of probation was redefined again so that the beneficiaries were understood to be no longer the probationers or the Courts but the potential future victims of their offenses (Garland, 1997). The emergence of a strong victims' support movement influenced perceptions of the aims of sentencing (Rock, 1991). It is also important to note that despite the increasing amount of risk talk in probation, no reliable or consistent method of assessing risk was made generally available to probation officers until around the end of the century.

Meanwhile, researchers in Canada and the United States, where many psychologists and researchers had never been convinced that 'nothing works,' were beginning to produce results that became very important for the next stage in probation's evolution. In particular, the new statistical technique of meta-analysis was being used to combine the findings of large numbers of studies to increase the reliability of conclusions, and meta-analytic studies of offender rehabilitation were clearly beginning to refute the dogma that 'nothing works' (Lösel, 2012).

The Second Challenge: 'Prison Works' and the Case of England and Wales

The early 1990s began what was to prove an era of turbulence for probation in England and Wales. Many similar developments can be found, for similar reasons, in other countries (see Kalmthout and Durnescu, 2008) but they appeared particularly strongly in England and Wales due to increased centralization of the management of probation and increasing political involvement in its development. The Probation Service entered the decade as a decentralized, locally controlled service guided by committees of local magistrates, equipped with a policy of diverting offenders from custodial sentences, the beginning of some new evidence-based ideas about reducing reoffending, and a traditional mission, set out in official documents, to 'advise, assist, and befriend' the people it supervised. By 2001, it was a national organization, controlled by central government, with an official mission that included 'the proper punishment of offenders' and a standard strapline on its publications, which read 'Enforcement, rehabilitation and public protection.' Although some commentators also point to continuities in the concerns and professional culture of the Probation Service (see Raynor, 2012), the change was quite dramatic and worth exploring in some detail.

In 1993, an unpopular Conservative Government replaced the minister responsible for prisons and probation, who had supported the policy of diversion, with a more right-wing politician, Michael Howard. He shortly declared in a major speech that "prison works," and set off an increase in the prison population that has continued almost without a break until the present. Probation needed a new brand and a new purpose in a suddenly hostile political climate, in which the training of probation officers was deliberately separated from that of social workers. Probation's leaders turned to the emerging research on 'what works' to support a new mission of reducing reoffending and managing risk. A survey by the Probation Inspectorate, carried out in the mid-1990s but not published until a new Government was in power (Underdown, 1998), found that much existing practice failed to incorporate the principles of effectiveness, which new research supported. A key influence at this time was the work of Canadian researchers, often summarized as the risk–need–responsivity model (RNR), which, with strong supporting evidence, argues that supervision should concentrate on higher risk offenders where it will make more difference; that it should address those features of offenders' circumstances and behavior that increase the risk of reoffending (known as 'criminogenic needs'); and that it should use methods appropriate to the learning styles of the people under supervision (with 'general' responsivity based on the common characteristics of offenders, and 'specific' responsivity based on distinctive needs of particular groups or individuals) (see Andrews and Bonta, 2010).

These developments led to a considerable shift in how rehabilitation was understood, and in the specific practices associated with it (McGuire, 2002; Raynor and Robinson, 2009). The new research pointed to methods based on

learning theory and particularly to cognitive behavioral approaches, often structured into 'programs' that followed a prescribed curriculum laid out in a manual. Moreover, the new focus on risk (both of reoffending and harm to potential victims) became too important to be left to the individual subjective judgment of practitioners. As risk management and risk reduction became central justifications for having a Probation Service, research was carried out on various structured approaches to risk assessment, and by the end of the decade, the Home Office had begun developing its own Offender Assessment System (OASys) for use throughout the prison and probation systems (now grouped together as 'correctional services').

Unfortunately, OASys proved to be so complex and burdensome that its potential benefits were never fully realized, and much of the information that should have been gathered for research was incomplete (Debidin, 2009). The fact that OASys took up so much time, so that probation officers were spending more time with their computers than with the people they were supposed to supervise, contributed to a generally negative response to risk assessment. For example, some people felt that it emphasized negative aspects of offenders' lives. Some evidence suggested that risks could be overpredicted, especially for women (Raynor, 2007) and that this contributed to inappropriate risk-driven styles of supervision (for some examples, see Carlen, 2002; for some alternative approaches, see Sheehan et al., 2007, 2011). In addition, some commentators associated the rise of risk assessment with changes in probation culture and more punitive attitudes toward offenders. The reality seems to be that these things can happen, particularly where unpopular innovations are introduced in an already punitive political climate, but some other studies also show that risk assessment methods that identify needs and targets for assistance can substantially improve effectiveness and support rehabilitation, when applied in a more favorable context (Raynor and Miles, 2007).

The focus on risk also led to the development of new forms of intensive surveillance and supervision for offenders assessed as dangerous or at high risk of doing serious harm. Collaboration between all relevant agencies was developed and organized through 'Multi-Agency Public Protection Arrangements' in which regular meetings of senior personnel organized supervision and monitored the behavior of offenders who caused particular concern. This relatively successful approach led, for example, to effective shared supervision by probation staff and police officers, which would have been unlikely in previous decades, and similar approaches to prolific property offenders who account for a disproportionate share of all crime. One major problem, however, is that the prediction of dangerous behavior is never as accurate as the prediction (itself only approximate) of general reoffending. There is always some risk left unmanaged and some serious offences committed by people under supervision, leading to criticism of all organizations involved in public protection (see, for example, Kemshall, 2008).

While some developments of the 1990s, such as the expansion of electronic tagging provided by private companies under contract to the Government, were primarily about surveillance and low-cost control outside prisons, a good deal of effort and resources also went into delivering cognitive behavioral group programs to probationers with a medium to high risk of reoffending. By the time a new Government was elected in 1997, and the Probation Inspectorate's Report on 'Strategies for Effective Offender Supervision' was published (Underdown, 1998), enough was known to allow a bid for significant Government funding for 'pathfinder' programs under a national Crime Reduction Program, which ran from 1999 to 2003. The aim was to roll out programs to all probation areas and deliver them effectively. The project of developing and evaluating such a large operation in only 3 years proved overambitious, and targets were missed in spite of the recruitment of unsuitable offenders to programs in an attempt to meet them. Not surprisingly, the outcomes revealed by research were not as promising as had been hoped. The general research verdict on the 'pathfinder' programs was that promising initiatives had been frustrated by poor and rushed implementation (Raynor, 2004).

While these substantial changes and developments were being generated within the professional world of probation, other rather different influences were brought to bear from outside, especially from the political realm. Politicians of all major parties in Britain were very conscious (perhaps over-conscious) of public concern about crime, which had risen rapidly during a period of mass unemployment in the 1980s. The politicians' response was to seek opportunities to present themselves as 'tough on crime.' Michael Howard was an early example, but many followed his lead, including the 'New Labour' Prime Minister Tony Blair. Now that the Probation Service was under the control of London-based politicians, they thought it simply did not look tough enough. Probation officers had always been required to take enforcement action if people under supervision did not comply with their probation order or aftercare license; for probation and other community sentences, enforcement took the form of prosecution for breach of probation and return to Court for possible resentencing. Some official reports suggested that this was not happening consistently, or enough, and politicians acted on this. A series of 'National Standards' documents starting in 1992 under the Conservative Government made enforcement requirements stricter and progressively removed the discretion of supervising officers over questions of when to take enforcement action. Breach rates increased and helped to swell the prison population. Furthermore, politicians thought that probation should be made to look more punitive: hence the insertion of 'punishment' into mission statements, the use of more menial physical tasks in Community Service, the visible identification of offenders doing Community Service by making them wear bright orange jackets, and the change of name to Community Punishment. Ambitious managers whose future careers depended on nimble self-alignment to the political climate helped to accelerate these processes, and the official branding of probation became more explicitly punitive.

So did the Probation Service's efforts to endure its own survival 'work'? By 2010, it was costing about £1 billion a year, serving a population of about 56 million people in England and Wales, with over 15 000 employees; it was supervising nearly a quarter of a million offenders on any given day, and preparing about 200 000 reports for the Courts in a year. Recent

research on accredited programs had begun to show much better results: when actual reconviction rates are compared to those statistically predicted for particular groups of offenders, the differences can be used to estimate the effect that a particular sentence or intervention is having, and by 2007, probationers required to undergo programs were reconvicting 10.3% less than the expected rate. For those who actually completed the programs (completion rates had risen substantially since the 'pathfinder' phase), the difference was 25.8% of the predicted rate (see Raynor and Robinson, 2009). However, other measures show a less encouraging picture. The use of both imprisonment and community sentences has increased in England and Wales since the early 1990s, while the use of fines has decreased. Therefore, if there is still much diversion going on, it is more likely to be diversion from fines than from prison.

Where Are We Now? Policy Choices and the Future of Probation

As comparative studies of probation show, England and Wales are not alone in these difficulties. In most countries, probation systems are looking for the right balance between a helping role and a law enforcement role, and locate themselves at different points along this continuum. England and Wales have an unusually strong emphasis on punishment, but the main policy dilemmas are similar in many countries (Kalmthout and Durnescu, 2008). Other developments are also widespread: for example, new technologies such as electronic tagging, including tracking tags, and even experimentation with 'kiosk' probation, which allows offenders to report to a machine rather than a person (*The Observer*, 29 April 2012). What these innovations lack is the element of personal guidance and help. Other developments concern the management and governance of probation services. For example, in England and Wales, the term 'offender manager' is now preferred to probation officer, and the Government is developing plans to allow the private and voluntary sectors to take over 70% of the Probation Service's current work (Ministry of Justice, 2013). In theory, these new providers will be paid according to how far they achieve reductions in reoffending. Many details of the policy remain to be worked out, but it is likely to represent the first major shrinkage in the scope and remit of the Probation Service in over a century. Probation services have always worked with the voluntary sector, and the private sector has built and operated a small number of prisons in Britain, but the wholesale privatization of the majority of probation work is a radical new departure that has led to concern about the legitimacy and accountability of new private sector providers (see the special issue of the *Probation Journal*, December 2012; Burke, 2012).

Some other developments, particularly in probation research, are more encouraging for people working in the field. The work of desistance theorists is proving influential (see McNeill et al., 2010): they study the process of desisting from crime, and promote approaches to supervision that support and facilitate desistance. Other ideas related to this perspective include an emphasis on probationers' own strengths and positive goals, to balance what some commentators see as an overemphasis on needs and deficits in the RNR model. While evidence to support these new approaches is limited, several studies have shown that skilled and efficient individual supervision makes a significant contribution to the reduction of reoffending below expected levels (see McNeill et al., 2010). This both helps to challenge overreliance on group programs and underlines the importance of appropriate individual contact and support for those who are engaged in programs.

Other developments have focused on the needs and experiences of particular groups of offenders in a diverse population. Research on 'what works' was originally based largely on majority white male populations in North American or European penal systems. It needs to be informed by further research and service users' views when applied to disadvantaged minority ethnic groups who are likely to have experienced discrimination and prejudice (Lewis et al., 2006; Bhui, 2009), or women, who constitute roughly half the population but a much lower proportion of offenders (Worrall, 1990; McIvor, 2004; Sheehan et al., 2007). There is evidence (reviewed by Hedderman, 2004) that risk factors and 'criminogenic needs' of women offenders overlap to some extent with those of male offenders, but with important differences. Patterns of offending are also different, typically involving a high proportion of minor property crimes such as shoplifting and resulting in lower rates of recidivism than those of male offenders. Recent studies of 'what works' with women offenders (for example, Sheehan et al., 2007, 2011) have emphasized the need for support and motivation, and for practical assistance with a wider range of personal and social difficulties than is typically found among male offenders. Such research supports approaches to supervision that are informed by an understanding of individual differences and socially imposed disadvantage. Overall, our level of knowledge about offender rehabilitation and the quality of the research base are both still improving, and both are arguably higher than at any time in the past. For example, the research network CREDOS, the Collaboration of Researchers for the Effective Development of Offender Supervision, set up in 2007, has active researcher members in 11 countries (see McNeill et al., 2010, which includes papers from the CREDOS conferences). The limitations and frustrations in the development of offender rehabilitation are often due to poor implementation of good ideas, or to policy and practice contexts distorted by external political pressures.

Conclusion

The future shape of probation seems likely to be determined not by developments within the field of probation itself, however promising, but by political choices reflecting the divergent political cultures of different jurisdictions. Countries with neoliberal governments and a neoliberal political culture tend to 'responsibilize' individuals and hold them accountable and culpable for most of the difficulties and problems they encounter in their lives: social causation is underplayed, and individual choice is all. Criminal justice systems in neoliberal

political cultures tend to emphasize punishment rather than rehabilitation or reintegration, and often have high rates of imprisonment (Cavadino and Dignan, 2006). Where more social democratic political cultures exist and social development and welfare are seen as a partnership between state support and individual initiative, assumptions about collective responsibility for managing social problems will often sustain a more rehabilitative and inclusive approach to criminal justice (Downes and Hansen, 2006). These might also be good environments for developments based on restorative justice, which is already the preferred option for young offenders in some jurisdictions, for example, Northern Ireland (see Jacobson and Gibbs, 2009). The choice between the two scenarios outlined in this paragraph ultimately rests with politicians, those who elect them, and other opinion formers within society. Probation staff and other professionals can prepare themselves and their organizations for future challenges by continuing research into what helps offenders to desist from offending, and communicating the results.

Problem Selection in the Social Sciences: Methodology

Wout Ultee, Radboud University Nijmegen, Nijmegen, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Sociological methodology has rules for testing hypotheses more severely, and for the formulation of theories rich in content. This article presents rules for problem selection by surveying cases from sociology's past and present. Among these rules are treating a seemingly small question as a subproblem of a larger one, expanding existing problem structures by adding new subquestions, revising a problem structure by a new overarching question, picking out contradictions between theories and research findings, and replacing false assumptions behind questions.

Social methodology textbooks state techniques of proper empirical analysis. For instance, they tell how partial coefficients of association are to be computed, adding that these coefficients provide a more severe test of multifactor explanations than bivariate associations. Books on theory building in sociology set standards for determining whether certain hypotheses are better than others. Logically unfalsifiable ones are out; future propositions should provide more information than current ones. Any science starts with problems. Are there precepts for selecting problems too? Yes, and this article draws upon principles intimated by sociologists (Lenski, 1966: p. 20; Blau and Duncan, 1967: pp. 9–10, 194–199, 402), proposed by philosophers of science (Bunge, 1967: pp. 165–221), and applied by sociologists to sociology (Merton, 1959; Ultee, 1980). These standards are elucidated by cases from sociology's past and present.

Overarching Problems and Subproblems

Durkheim 'was not interested in suicide at all,' so says Collins' (1994) textbook on sociological traditions. But then, why did Durkheim dub his 1897 study *Le Suicide*? Weber in 1910 grumbled that his critics understood him to explain the rise of capitalism fully from the ethos of Protestantism, and retorted that he only dealt with the question of whether this ethos fitted the spirit of entrepreneurial capitalism. Yet in the 1920 preface to his collected papers on world religions, Weber's interest was rationalization processes, including the rise of capitalism. These changes had gone furthest in the West, and Weber wondered why.

If these two stories about sociology's questions carry a moral, the lesson is not that persons nowadays regarded as sociology's founders, did not know what they were up to. The message amounts to a methodological command on meritorious problems. Durkheim grasped that seemingly small questions become pertinent when taken as subproblems of larger ones, and Weber understood that it is wise to divide mammoth problems into more modest ones, and those in their turn into even more tractable questions. Durkheim and Weber entered sociology's hall of fame because they pointed toward a bunch of smaller questions falling under one and the same heading. The subtitle of *Le Suicide* runs *Étude de sociologie*, lifting a phenomenon from psychology into that science which studies societies – and the extreme case of leaving them.

Problem Structures and Their Dynamics

For Durkheim, a society's suicide rate tells about its cohesion; the higher this rate, the less cohesive a society. Weber observed that a society's inhabitants do not always use their economic freedoms, for instance, those of enterprise and labor, and supplemented the problem of how these rights got included in a society's code of law, with the problem of the strength of a person's motivation to use these liberties. Both questions were part of the question of why entrepreneurial capitalism arose in the West. In its turn, the question of the rise of capitalism, including bankers' as well as entrepreneurial capitalism, was a subquestion of the even larger question of the speed of rationalization processes in the West during the last couple of centuries.

In Durkheim's *oeuvre*, the question of a society's degree of cohesion also comprises long-term trends in the prevalence of economic exchanges when comparing Ancient Israel, the Roman Empire, and medieval Burgundy, and the degree to which assemblies of hunters and gatherers are religious in nature. Weber's question of rationalization led to less grand ones on the rise of science and the bureaucratization of states. Any methodology of problem selection should contain the rule that questions should not be judged on their own, but according to their place in a structure of overarching problems and subproblems. However small a problem seems, it has more appeal if it is part of an overarching problem. And however towering a question appears, it grows less scary if it is broken down into subquestions.

The Durkheimian Problem Structure

Figure 1 depicts the Durkheimian problem structure. The novelty of *Le Suicide* was not simply that Durkheim turned the question of suicide into a subquestion of the larger one of societal cohesion. Hobbes (1651) took order and its opposite violence as the master problem of those studying the body politic. For him, civil wars and wars between sovereigns were part of the problem of order and violence. Next to it, Durkheim placed the problem of the presence and absence of ties between a society's members. The counterpart of the question 'why do people not always live in peace?' is not only 'why do they sometimes use violence?' but also 'why do they sometimes live relatively isolated from each other?' For Durkheim, suicide was the supreme example of severing the ties between persons and the society in which they live.

Figure 1 The Durkheimian problem structure and its dynamics.

Apart from *Le Suicide*'s question, Figure 1 encompasses the questions guiding Durkheim's two other main studies. *De la division du travail social* from 1893 focuses the frequency of economic transactions between a society's members at various points in history. It narrows this question down to that of the degree to which cooperative law (civil law regulating economic contracts by restitution) is more widespread than criminal law (penal law involving repressive sanctions). *Les formes élémentaires de la vie religieuse* from 1912 notes that Australian aboriginals disperse when hunting and gathering their food, and asks to what extent their leisurely meetings celebrate a totem and turn them into members of one society. Durkheim's questions involve a shift from questions on economic ties, by way of questions on coliving, to questions on religious ties, yet they always pertain to societal cohesion.

Given the Durkheimian problem structure, later scholars can raise questions on types of attachment to which Durkheim paid limited or no attention. Examples are questions on changes in the rates of marriage, birth, and divorce in industrial societies. A wedding creates a sexual and domestic bond between two members of the opposite sex, divorce dissolves it, and a higher birth rate amounts to more parent–child relations in a society. focuses on the making and undoing of sexual and domestic ties. These monographs amount to a new branch of the Durkheimian problem structure.

The Weberian Problem Structure

The Weberian problem structure and its dynamics are given in Figure 2. The overarching problem is that of rationalization, and Merton (1938) pursued the subproblem of the rise of science in the West, and Blau (1974) that of bureaucratization. The art historian Gombrich (1960) studied questions on the skills of painters to furnish a faithful representation.

Figure 2 The Weberian problem structure and its dynamics.

The relation between problems as depicted in Figures 1 and 2 are logical in nature. An overarching problem, usually by way of uncontroversial auxiliary assumptions, implies subproblems. It is another, and less important, matter whether a person raising a subproblem of an overarching problem of an earlier scholar studied under that master or read a book by her or him. Merton and Blau took the lead from Weber; Gombrich was not influenced by him. Weber invokes Heinrich Wölfflin once when discussing the question of representational skills; Gombrich quotes Wölfflin frequently.

As stated, the step from an overarching question to a subquestion involves largely undisputed assumptions. Few would argue that capitalism is less efficient than slavery. Yet this proposition was belied by Fogel and Engerman's (1974) test for the American South shortly before slavery was abolished. A scholar working on a question can make progress by replacing these auxiliary assumptions by better approximations. Weber did not do so, but Durkheim did. In countries prescribing suicide under certain circumstances, suicide is not an instance of low cohesion, but of strong solidarity. In that case, Durkheim spoke of altruistic suicide.

Behind Weber's distinction between bankers' and entrepreneurial capitalism lurks evidence speaking against the hypothesis that the rise of capitalism is always accompanied by the growth of banking. Protestant businessmen did not take out loans. Their religion put a premium on frugality, and contributed to reinvestment of profits in their enterprise. The background of Weber's distinction between laws granting people economic freedoms and the use of these freedoms by a society's members forms the observation that people sometimes do not use their rights, as well as the hypothesis that they exercise these rights only if they are motivated to do so. Classical economics assumed that every person had this drive; Weber held that Protestantism strengthened it. A wise rule is to state the background of a question as fully as seems necessary for bringing out a problem structure.

The Weberian Problem Structure Radically Revised

The division of an overarching problem into subproblems may drastically alter. Studies by Smith (1776), Elias (1939), Samuelson (1954), Van den Doel (1979), and De Swaan (1988) imply the revision of the Weberian problem in Figure 3. Weber never made clear what state bureaucracies were doing. States possess the legitimate monopoly on the means of violence; Elias added that states wield the legitimate monopoly on taxation. Were all taxes spent on armies, police, and prisons? This obviously is not the case. Here, the hypothesis is useful that markets make for the optimal production of individual goods (Smith), but not for the optimal production of collective goods (Samuelson). The production of collective goods approaches optimality in a state with universal suffrage and a bureaucracy that executes its laws (Van den Doel).

De Swaan listed collective bads and laws contributing to their elimination and to the production of collective goods. First, poverty is a collective bad. Poor people are more likely to trespass the law, and crimes form a general threat to life and property. Following De Swaan, this danger is alleviated by state insurance against disability and unemployment. Contagious diseases amount to a second collective bad. If local authorities provide each household with piped water and an outlet on the sewers, public health improves. Third, compulsory schooling lowers the percentage of children who cannot read and write, and makes for a more optimal functioning of markets and bureaucracies. Weber's conception of the state is saved by the assumption that armies, police, and prisons avert collective bads. Armies lessen a threat to a state's independence, police patrols contribute to safety on the streets, and prisons deter.

Problem Structures and Theories

As the saying goes, a question well put is a question half answered. If it is clear that some problem is part of a larger problem, and if a solution for the overarching problem is at hand, a possible solution to the smaller problem is available too. But then, if an answer to a particular smaller question of a larger one turns out to be false, the opportunities to disestablish a solution to another subproblem of the larger one increase. Additionally, the notion that problem structures exist and have a dynamic makes the project of sociology have more continuity than suggested by Boudon (1979) and Gove (1995).

Figure 3 The Weberian problem structure radically revised.

They accepted that sociology's questions to outsiders show a bewildering variety, and bypassed the possibility that one and the same larger question may harbor a host of seemingly disparate questions.

Contradictions and Issues

One way of formulating a problem in a more useful way is to ascertain its place in a problem structure. Are there much injunctions for problem choice? Sociologists debating sociology have argued about the primacy of theory versus the supremacy of research. In contrast, Popper (1962) defended that every science, including sociology, most fruitfully starts with contradictions between general hypotheses and specific research findings.

Contradictions – or, to use (Kuhn's 1962) terms, puzzles and anomalies – contribute to sociology's growth. For Merton's (1973) sociology of science, the prevalence of priority disputes in a field was surprising in several respects. Its explanation was not the egotism of the scientists having made discoveries, since their part in the disputes was small. Nor was it to be accounted for by the increasing competition between scientists, since the frequency and intensity of priority disputes in the West decreased over time. A rule of method runs: single out contradictions.

Incompatibilities between hypotheses also invite new research and theorizing. They sometimes are called issues, but that term also refers to false alternatives. An example is the question of whether intelligence is determined by social or by genetic factors. Intermediate positions are possible, the list of social factors may be incomplete, and the location of intelligence on genes may be unknown. Popular science states issues in a metaphorical way; are we born with a brain hardwired with rules for language, or is the brain a big sponge, capable of creating rules for language by mopping up what we hear?

The phrasing of a contradiction problem sometimes contains seeds for its solution. For instance, Huizinga (1941) asked how it was possible that painting and other forms of culture flourished in the Netherlands during the seventeenth century, so shortly after this society became independent from Spain. His answer was that Dutch culture blossomed because the Netherlands was a new state. In states that have recently become independent, the upper strata have risen from the lower and the more open a country's elite, the more its culture will flower. Trevor-Roper (1976) wondered how it was possible that an emperor as preoccupied with expanding his territory as Charles V (1500–58) furthered the art of painting so much. In the end, Trevor-Roper surmised that Charles V commissioned paintings to the extent that, and precisely because, they legitimated his political power.

Apart from the rule for theory building to mobilize the information in a contradiction problem, there is the precept to turn the problem around. Rather than asking why the number of unruly passengers on airlines is increasing, it might be worthwhile to ponder why this number until now did not increase much more strongly. A more academic example is as follows. Marxism noted that a lot of workers refrain from joining unions and strikes, and raised the question of how workers come to have a false consciousness. Olson (1965) held that unions and strikes produce collective rather than private goods, applied the prisoners' dilemma from game theory in mathematics, predicted that rational workers would not strike, and raised the question of why people participate in social movements. However, it should be clear that any theory with some substance to it should explain that some people join labor unions and certain others do not.

Strings of Questions

The terms problem and question sometimes are used interchangeably, referring to queries of any specificity. However, everyday usage of expressions like object of investigation, task, question, and problem suggests that some inquiries are more focused than others. What does the articulation of problems involve?

Problem Articulation

If it is maintained that sociology is about societies (and not about human beings taken on their own), it sometimes is said that the object of research has been stipulated. Yet no single feature of this unit has been singled out for explanation. If this property is taken to be, say, the 'functioning' of a society, the object of inquiry turns into what has been called a task. Yet the circumscription of this aspect remains limited, since the term does not focus any particular way of functioning. If a distinction is made between optimal and suboptimal functioning, the study involves a question, with that term being taken in a narrow sense. Of course, other types of functioning may be distinguished too. Questions in their turn do not allude to possible causes. If research on some sample of societies determines the extent to which less stability in a society's environment goes together with a less optimal functioning of this society, the matter at hand is articulated so fully that the problem now is whether some logically falsifiable hypothesis is true. Putting a question mark behind a falsifiable proposition amounts to posing a problem in some narrow sense of that word.

The example of a string of increasingly articulated queries just presented neglects any difficulty in obtaining measurements for the degree of stability in a society's environment, and the extent to which the functioning of a society approaches optimality. It has been held that questions should refer to directly observable phenomena only, and in the human sciences therefore to outward behavior and not to mental states. This rule is a leftover from a wrongheaded empiricist philosophy of science. All terms to some extent are theoretical, and any proposition whatsoever, whether about acts or thoughts of persons or processes and situations within of societies, never can be definitely proved.

From Descriptive to Explanatory Questions

There are strings of questions of another kind. A researcher's early questions often are descriptive: how many of the people

living in 1972 Britain and born to working-class parents had moved up to the higher classes? A follow-up question might be whether this probability to climb equals the chance to descend from the upper to the lower classes. A yet later question presupposes the answers to both earlier questions, and seeks to ascertain whether upward and downward mobilities were as prevalent in 1949 as in 1972. By raising additional descriptive questions, narratives become richer.

At some point, researchers leave descriptive questions behind them, to raise explanatory questions. The explanatory question following up on the previous string of descriptive questions ran as why was during the 1970s upward mobility less widespread in Britain than in Sweden, and more widespread than in France? The obvious answer to that question was that left-wing governments make for more upward mobility (Heath, 1981; Goldthorpe, 1987). And after a comparison of upward mobility in several industrial societies at the same point in time, the follow-up question may be raised how these societies compare over longer periods (Erikson and Goldthorpe, 1992; Breen, 2004).

From Superficial to Deeper Explanatory Questions

Some explanations 'scratch the surface only,' others delve deeper. Why would particular ideologies make for more upward mobility? Just like individuals, governments cannot always attain their goals. By which means then do social-democrats attain the goal of more upward mobility? Does Sweden have more upward mobility than Britain, because social-democrats make children branch out at a later age to schools that demand more or less of pupils? Or is this the case because social-democrats pursued a policy of full employment? And then, if the answer to the first question is 'no' and that to the second one 'yes,' why would there be more upwardly mobile persons in a society without unemployed persons?

There is no obvious point at which the hunt for deeper explanations should stop. Some theoreticians in effect defend that 'the buck stops here.' No one nowadays seriously defends that propositions about societies are logically independent from propositions about individuals. However, whether rock-bottom explanations of the features of societies always should refer to the motives and aversions of a society's members, as well as the opportunities they have and the barriers they face, is controversial. In the discussion on 'methodological individualism' (O'Neill, 1973), the borderline between methodological rules and substantive requirements was violated. Perhaps it is wise to no longer state this debate in terms of theories explaining societal phenomena, but to settle it by recognizing that short-hand statements of sociology's questions refer to societal features only, but that these questions, if they are stated fully, always refer to the persons making up a society's population, that is, to individuals and societies (Ultee, 1998).

From Meager to Thick Descriptive Questions

Some descriptive questions – and their ensuing explanatory questions – can be meager, whereas others aim for lavishness. Thus, it often has been ascertained that no society ever has been and ever will be completely egalitarian. As Lenski (1966: p. 20) maintained, in the debate between the conservative and the radical tradition in sociology, it is possible to make headway by transforming problems stated in a categorical way into problems phrased in variable terms. It may indeed be the case that full equality never has been observed in any society; however, is the lowest degree of inequality observed until now the lowest that is possible? And do long-standing differences between highly industrialized countries in their ruling ideology explain differences in their degree of income inequality? Questions about equality that demand 'yes' or 'no' are less precise than questions about degree of inequality.

Following Lenski, progress also can be made by breaking down the compound concepts contained in problems into their constituent elements. Thus, the question of whether power – in the singular – determines privilege – in the singular – will not do. Rather, the question is to what extent differences in the consumption of a certain good in a particular society depend on the control of various resources. When answering this question, Lenski distinguished the skills of hunters and gatherers, the size of gardens in horticultural and of fields in agrarian societies, the possession of metal weapons, the private ownership of machines, the technical skills of the people designing machines, the range of legitimate command accruing to a political position, and the right to vote in elections. Lenski also suggested that the change from agriculture to industry was accompanied by a shift in the right to vote. Once elections were infrequent with only the propertied classes having the right to vote, whereas nowadays there is universal suffrage for periodic elections. By breaking down compound problems into their constituents, thick descriptions and detailed explanations are obtained.

Erroneous and Well-Stated Questions

If descriptive questions are logically prior to explanatory questions, explanatory questions may be wrong. Answers to questions can turn out false, questions themselves may be mistaken. The question of why in the 1970s social mobility was more widespread in France than in Sweden is erroneous, since in that decade mobility occurred more often in Sweden. The Olson question of exactly which selective incentive makes persons protest against the hunting of seals assumes that some selective incentive is always at work, which may not be the case. This example suggests that if a rock-bottom explanation slips into a question, that problem turns into leading question.

Methodological rules that stipulate conditions banishing erroneous questions and guaranteeing well-stated ones seem doomed. It is wise to review the presupposed description, but checking has to stop somewhere. In this respect, it is interesting that the answer to an explanatory question always implies that the original question may not have been fully right. When Durkheim asked why Protestantism goes together with more suicide than Catholicism, he devised the hypothesis that more tightly knit religions show a lower suicide rate. To derive what he wished to explain, Durkheim assumed that Catholics are more integrated than Protestants. He knew that this assumption was off the mark for England, since the Anglican Church

was a state church. Yet in this way, he could account for England as the deviant case to the regularity he wished to explain. Malewski (1964) showed with examples from social psychology that every explanation of a regularity predicts conditions under which exceptions occur to the regularity to be explained.

Duncan held that the question of factors influencing the chances that the members of a society move up or down poses the issue poorly. The prime factor is father's occupation. However, the proposition that the lower the occupational prestige of a person's father, the higher this person's chances of upward mobility forms a truism. After all, the hypothesis thrives on bottom and ceiling effects. To test more interesting hypotheses, according to Duncan, questions on change in a person's life should not be stated in terms of some difference score, but as questions on the strength of the relation between a person's earlier and later score, and on the factors influencing that relation.

Undertheorized Questions

Schütz (1932) raised the question of why human beings understand one another, and did so with a certain urgency by phrasing his question as 'how is it possible that people understand each other?' This query sounds like a contradiction, although casual observation suggests that some people at some places and in some times indeed understand one another. However, no particular hypothesis has been derived from a specific theory holding that it is impossible for human beings to understand each other. Thus, the theory rendering the question compelling is lacking. The Parsonian problem of how order is possible (Parsons, 1937) is undertheorized in a similar way. Any derivation of the hypothesis that society is violent, from the principle that persons follow their interests, involves additional assumptions. These can be wrong, which makes the question of how order is possible less pressing than it sounds. Indeed, a full statement of the question 'how is order possible' implies the conditions under which order occurs, and those under which it does not.

Research of the past decades not infrequently addressed the question of whether the association observed in a cross-sectional sample of a society's inhabitants between their year of birth and a particular characteristic is to be accounted for as an age, cohort, or period effect. As methodologists point out, this question is undertheorized too. The available hypotheses do not predict some age effect, some cohort effect, and some period effect. Those hypotheses are so vague that their conjunction is almost if not fully logically unfalsifiable. The hypotheses at hand have more substance; if people marry, grow up in lean times, and live through a war, then their values will be less postmaterialist (Inglehart, 1977). Those variables can be independently ascertained, making statistical models identifiable.

Conclusion

What are the prospects for more attention to problem selection in scholarly studies on human societies and in social methodology books? Since 1998, there is an English language textbook aiming to state (and answer) sociology's questions: *Sociology, The Central Questions* by Kornblum. One of its questions runs as "Stratification and social class, are they inevitable, or can there be a classless society?" This question may be taken as erroneous, yet the text following it makes clear that students are taught to think in gradual instead of categorical terms about inequalities. Nevertheless, this type of textbook does not seem to have caught on. As to review articles, some now distinguish generations of research. They do so not only by pointing toward more advanced techniques for data analysis and new theories, but also by invoking problem shifts. Ultee (2006) did so in research on the theme of welfare states and inequalities, and Knutsen (2007) in research on class voting. But this type of review articles has not become common yet.

Lieberson (1985) subtitled one of his social methodology books 'the improvement of social research and theory,' but pointed toward the prevalence of 'unanswerable questions,' and he pleaded for social researchers to avoid them. Abbott (2004) sought to complement rules for testing hypotheses by stating rules for thinking them up. For this, he took his inspiration from Pólya's (1957) *How to Solve It*, with it being a problem. But in the final chapter, Abbott, fortunately, was concerned with 'how to pose it,' that is, how to arrive at interesting problems, pointing toward puzzles. Firebaugh (2008) presented seven rules for good social research. At first sight, none of them refers to problems. But upon studying the argument, it turns out that Firebaugh repeatedly points toward erroneous questions. His prime example is the question of why income disparities on a worldwide scale have been growing for the past few decades, whereas they have been declining (although they have been rising in most countries of the world taken on their own). Upon closer inspection, this example also illustrates the rule that a question well put is a question half answered (the rise in average income has been strongest in the poorest and most populous countries).

In everyday life, researchers consider some problems difficult, others significant, and yet others exciting. These notions are difficult to put into formal rules. However, a more difficult problem might be taken as an explanatory question to which several solutions have been proposed, none of which worked or led to closer approximations. Thus, difficult problems are specific kinds of Popperian contradictions. Also, a structure consisting of overarching problems and subquestions goes some way toward formalizing the intuition that a problem is significant. Perhaps a problem area is called exciting, if, after many a failed attempt, the solution of an overarching problem seems near, because progress is being made on subproblems.

Of course, it may be argued, with Ziman (1987), that the question of how scientists choose their problems is erroneous, since most researchers do not have a choice. Their problems are pregiven by the organization that employs them. This observation does not do away with the question of problem choice, but makes the question of the formal rules for problem choice by the higher authorities of these organizations more pressing. The methods outlined above should be taken not only as principles for researchers who have a choice, but also as precepts for institutes run on a budget, and for foundations that award subsidies.

Problem Solving and Reasoning: Case-Based

David Leake, Indiana University, Bloomington, IN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Case-based reasoning (CBR) is a paradigm of artificial intelligence and stance for cognitive science research. CBR models the reasoning process as primarily memory based, taking retrieved prior cases as a starting point for solving new problems and interpreting new situations. Fundamental problems include how to guide retrieval of relevant cases and how to adapt them to new needs. The CBR perspective is shaped by studies of human cognition, but the resulting approach has proved effective for developing applied intelligent systems in a wide range of domains. New directions include efforts to harness experiential knowledge on the Internet.

Case-based reasoners solve new problems by retrieving stored 'cases' describing similar prior problem-solving episodes and adapting their solutions to fit new needs. As case-based reasoners process each problem, they learn by storing records of their problem solving as new cases to guide future reasoning. Case-based reasoning (CBR) research studies the CBR process both as a model of human cognition and as an approach to building intelligent systems. Principles from CBR research serve as a foundation for applied computer systems for tasks such as supporting human decision making, aiding human learning, and facilitating access to electronic information repositories.

CBR as Cognitive Model

A major motivation for initial research on CBR was the observation of how humans remember, reason, and learn from experiences. Studies of story understanding by Schank and others noted that people who encounter surprising events are often reminded of similar past events, which they use to help them understand and respond to the new situations. Studies of reminding events investigated human memory organization, giving rise to dynamic memory theory (Schank, 1982), which included theories of how episodes are organized and indexed in human memory to be retrieved across different contexts, and the circumstances under which reminding events are triggered. Reminding events are often failure driven, occurring when expectations are violated. For example, a doctor whose patient's condition plummets after taking a medicine might be reminded of a previous patient's similar reaction.

Failure-driven reminding events can facilitate learning by providing additional data as a basis for generating and testing candidate explanations. They may also provide information about past solutions; remembering how the past emergency was treated may suggest a treatment for the new patient. Even if the past solution does not apply directly, as when the new patient is allergic to the drug used in the previous case, it may suggest a class of drugs to use. The flexibility to apply prior cases to solve new problems arises from flexible retrieval – the ability to retrieve cases that are relevant, even if they reflect different circumstances – and adapting their solutions as needed to fit the new situation.

Being reminded of prior problem-solving failures can be useful as well. When a doctor is reminded of a mistake or failed treatment, remembering the outcome of the previous treatment helps to predict the new outcome and warns of potential pitfalls to avoid. Thus CBR supports learning from either successes or failures.

Psychological studies provide evidence supporting human CBR for problem solving in a wide range of tasks such as learning programming, performing mathematical problem solving, explaining anomalous events, and decision making (see Leake (1998) for examples of this work).

CBR also plays an important role in human cognition for classification and interpretation. For example, in legal reasoning in the American legal system, prior cases are the basis for legal judgments: lawyers build arguments about how to interpret rules of law by comparing and contrasting precedent cases to the current situation (see Ashley and Rissland, 1988).

Research on CBR as a cognitive model studies the knowledge and processes that underlie human CBR, addressing topics such as memory organization, similarity assessment, and analogical mapping (Kolodner, 1993; Leake, 1998). Computational models developed in this work illuminate functional constraints on reasoning processes and can provide testable hypotheses about human reasoning for psychological investigation.

Understanding of human CBR process is closely related to understanding of similarity and analogical reasoning and learning. A summary of the relationship of CBR to psychological research on analogy is included in Mantaras et al. (2005).

CBR as an Intelligent Systems Approach

Apart from cognitive science, CBR has been studied as a knowledge-based systems approach to developing intelligent systems. The use of CBR in intelligent systems is motivated both by considerations for system development and for user interactions. Some key motivations are to facilitate knowledge acquisition, to facilitate knowledge maintenance, to increase problem-solving efficiency and solution quality, and to benefit user acceptance. Knowledge acquisition is a classic problem for rule-based reasoning. Some domains are hard to codify in

terms of the general rules assumed by rule-based systems; for example, domains in which rules would require too many exceptions. In general, acquiring rules from experts is difficult, as they find it hard to characterize their reasoning in rule-based form.

However, experts find it natural to share their 'war stories' of experiences, and those experiences correspond to cases. Such cases need not capture the entire problem-solving structure of the situation, but instead need only to include the information needed to determine applicability and to enable adaptation of the old solution to new circumstances. This is not to say that CBR avoids all knowledge acquisition issues: in CBR, traditional rule acquisition issues are replaced by issues of capturing and representing reasoning episodes, selecting similarity and indexing criteria, and capturing case adaptation knowledge. However, in practice, these may be more tractable.

In addition, the initial case knowledge of a CBR system need not provide complete coverage of the problem space. Systems can be fielded with a limited set of 'seed cases,'which are augmented by acquiring missing cases when existing cases prove inadequate during problem solving. Only the parts of the problem space in which problems arise in practice need to be covered.

CBR can provide efficiency benefits when problems are time consuming to solve from scratch, but stored cases provide a sufficiently close starting point to be easily adaptable to new needs. For example, generating a new home design may be expensive, but customizing that design to reflect customer preferences (e.g., by changing kitchen appliances) may be simple. Quality benefits arise from the benefits of experience. The successful prior use of a previous case attests to its quality; the debugging needed to apply it in the past is automatically incorporated, avoiding repeating past mistakes.

User acceptance is furthered by the ability of CBR systems to provide natural explanations of decisions by accounting for decisions in terms of actual previous examples, rather than in terms of rules that users may not understand or trust.

Steps in Case-Based Problem Solving

Computer CBR systems have been developed for numerous tasks including planning, design, and explanation. Regardless of the specific reasoning task, any case-based problem-solving system follows the same basic steps, referred to as the CBR cycle. In the basic CBR cycle, the system receives a problem, generates indices for retrieval and retrieves candidate cases, assesses their similarity to the new problem, adapts their lessons to fit the new situation, evaluates the result (possibly repeating adaptations as needed until the result is satisfactory), applies the result, and retains a record of the problem, solution, and outcome, as a new case to guide future reasoning. The retention of cases at the end of the cycle means that in CBR, learning is a by-product of every problem-solving episode. Thus computer models of CBR must account for four main processing steps: retrieval/similarity assessment, adaptation, evaluation/application, and storage. The process is sometimes characterized by the 'four REs': retrieve, reuse, revise, and retain (Aamodt and Plaza, 1994).

Retrieval

In order to facilitate retrieval of relevant cases, stored cases are organized by indices characterizing circumstances in which the cases are likely to be relevant. For example, in a medical CBR system to suggest treatments for illnesses, treatment cases could be indexed by the diseases they treat and the characteristics of patients (e.g., age) that tend to determine whether a given treatment is appropriate. The indices for a given domain may be determined by knowledge engineering or learned, for example, by induction or by generating explanations to determine feature importance. Cases capturing structured information (e.g., plans or workflows) may be indexed by substructures as well as content-based flat indices.

Given a new problem to solve, a case-based reasoner first performs situation assessment to analyze the input problem and describe it in terms of the indices used to organize cases. For example, in a medical context, rather than trying to diagnose based only on the patient's current vital signs, it may be important to derive more abstract features such as 'deteriorating condition,' based on consideration of the patient's history.

Retrieval algorithms use the description to retrieve the cases in memory expected to be most relevant. For example, nearest neighbor retrieval algorithms select the most similar prior cases according to a metric that weights features by their relative importance. Alternatively, case libraries may be organized into discrimination networks to enable retrievals based on only a small number of feature comparisons. After candidate cases have been retrieved, a finer grained similarity assessment process is often used to identify the best candidates and to determine differences between the old and new situations, for which the old solution must be adapted.

Sometimes a complete problem description is not available at the start of problem solving. For example, for diagnosis, the symptoms that are relevant may be unknown until the problem is diagnosed. Such problems can be addressed by conversational case-based reasoning (CCBR) (Aha et al., 2006). CCBR is an incremental process, which begins with the user providing an initial input, from which the system identifies a preliminary set of relevant cases and determines features most relevant to discriminating between those cases. The user is presented with a list of questions about those features, ordered by their expected usefulness, and can choose which of those questions to answer. The user can also examine any of the presented cases. Each time the user answers a question, the system revises the list of questions and cases, taking into account the new information to narrow down candidate cases. The cycle terminates when only one case remains (i.e., when a unique case matches the problem description), when cases are exhausted (i.e., when no case sufficiently matches the problem description), or when the user is satisfied with one of the cases from the set of candidates and chooses not to continue the dialog. CCBR question selection algorithms are designed to minimize the expected length of the dialog, given the system's cases. Question selection may also reflect information about user characteristics and contextual factors, such as the difficulty of providing answers to particular questions. For example, in a medical diagnosis system, the system might favor easy-to-answer questions over those that can only be answered by invasive tests.

Case Adaptation

The case adaptation step revises the lessons of the retrieved case (or revises and combines the lessons of multiple retrieved cases) to generate a new solution. Adaptation may involve operations such as transformation of the structure of a solution or substitution of components. For example, a doctor might combine elements of prior treatments to address multiple complaints, or might adapt the treatment used for an adult to a treatment for a child by substituting a medication approved for children. Adaptation may also require operations such as numerical adjustments, for example, to reduce an adult dosage to suit a child.

CBR systems often use rule-based methods to transform prior solutions, applying general adaptation rules. Model-based reasoning has been applied to guide adaptation based on causal structure, for example, when adapting device design cases. Constraint satisfaction methods have been used to assure that adaptations respect problem constraints. CBR has been applied to the case adaptation problem itself, to capture and reuse adaptations performed by a user and for speedup in learning from adaptations that the CBR system generates by other methods. An alternative approach to case adaptation is to use derivational analogy to account for new circumstances by replaying a prior solution generation process rather than revising a prior solution (Veloso, 1994).

In interpretive CBR, the case-based reasoner does not modify the retrieved case, but instead develops justifications for why the prior interpretation applies (or does not apply) to the new situation. For example, in legal reasoning, a reasoner aiming to apply a precedent may develop justifications for why apparent differences are not important. Justifications may also account for why particular features should take precedence. For example, if CBR is being used to predict whether a person will find a particular movie enjoyable, justifications could compare the movie to one the person enjoyed previously, assessing not only the similarities and differences but also the relative importance of those aspects.

Evaluation/Application

Tentative results of case adaptation are evaluated to assess the appropriateness of the new solution and to determine whether additional changes are needed, possibly resulting in a cycle of repeated adaptation and evaluation. Once a solution is judged acceptable, it is applied to the real problem. If the solution fails, it may be repaired, reevaluated, and reapplied.

Storage

Each processing episode of a CBR system, whether resulting in success or failure, is stored to guide future reasoning. Cases containing successful solutions suggest solutions for similar future problems, while cases storing failures provide warnings of problems to avoid and information on how to avoid them. The storage step packages information about the problem, solution, and its results in a new case. It also assigns indices for the case and places it in the case library (also called the 'case base') for future use. CBR systems retain cases in an ungeneralized form, enabling storage of the case itself with minimal processing. However, to enable stored cases to be reused in a wide range of circumstances, CBR systems often generalize the indices under which cases are stored. The storage step may involve decision making about whether it is worthwhile to retain the new case (e.g., whether it provides new coverage).

Research issues

Retrieval and Similarity Assessment

Effective case retrieval depends on appropriate retrieval algorithms, well-organized case bases, and indices that are useful for the current task. In case-based problem solving, cases are indexed by information about the problems they solve. For example, a case-based planning system may index plan cases by the goals they achieve and constraints they satisfy. Indices should be predictive of the relevance of cases and should involve features of problems that are likely to be known to the reasoner; both abstract and concrete features may be useful. A crucial research issue in CBR is developing appropriate indexing vocabularies for particular reasoning tasks. In order to retrieve useful cases for novel situations, methods are also needed for reformulating or transforming indices to widen search when no directly relevant cases are available.

CBR research has also explored replacing traditional measures of similarity with similarity criteria that directly reflect pragmatic needs. A basic tenet of CBR is that similar problems will have similar solutions; this premise is expected to lead to similar cases being a better starting point for generating new solutions. This is normally viewed as reflecting a commonsense belief about the ease of adaptation: the solution for a similar problem will require less adaptation to generate a new solution than one that is less similar. However, it is not necessarily true that the reasoner's similarity criteria (generally based on semantic similarity) will actually ease adaptation, which has led to studies of how to link retrieval directly to adaptability (Smyth and Keane, 1998).

Research on retrieval algorithms investigates methods for achieving rapid retrievals from large case bases (e.g., by exploiting parallel algorithms). From the perspective of cognitive science, there has been much interest in the types of features that are relevant to human retrieval and the processes by which analogies are mapped to new situations.

As CBR has been explored in areas such as recommender systems, retrieval criteria beyond similarity have become important. For example, in product recommendation, it may be valuable to provide a varied collection of options, making it important to balance similarity and diversity. Likewise, different users may have different preferences, making it important to personalize the information presented to the user.

Case Adaptation

Developing case adaptation rules is often difficult because of knowledge acquisition problems: the needed knowledge may not be available or may be difficult to codify. Consequently, improving case adaptation methods is a fundamental challenge for CBR. Research areas include applying machine learning techniques to automatically generate case adaptation rules; applying CBR to a CBR system's internal processing, to adapt

cases based on prior adaptation experiences rather than rules; and using data mining and web mining methods to generate new adaptation knowledge or to support the adaptation process on the fly. It is important to note that sufficiently powerful case adaptation can enable cases to be used in very novel ways; research on flexible retrieval and adaptation processes has given rise to CBR models of creative problem solving.

Case-Base Maintenance and CBR System Maintenance

As CBR systems receive long-term use, keeping the case base accurate becomes an important problem. Likewise, as cases are accumulated, it may be necessary to reorganize or update the case base in order to improve its coverage of important problems and to avoid slow retrievals. This has led to considerable interest in methods for improving case quality and retrieval efficiency by strategic deletion, revision, and addition of cases to a case base. A major focus of this effort has been based on the idea of competence-based deletion, first proposed by Smyth and Keane, in which a CBR system reasons about which cases can be deleted with minimal risk of lost coverage (see Leake et al. (2001) for a sampling of this area). Because cases are increasingly generated by multiple distributed sources (e.g., different offices of an organization), additional issues are arising on how to update and access distributed case information.

In long-lived CBR systems, the case base is not the only knowledge container that must be maintained. For example, indices may need to be adjusted, similarity criteria may need to be changed, and source selection criteria for external knowledge sources may need to be revised, each giving rise to a current of research.

Integration with Other Methods

CBR systems may be integrated with other systems and approaches – both artificial intelligence systems and other systems – to leverage off the strengths of each. For example, case-based and rule-based reasoning may be integrated with each other, with cases used to guide interpretation of rules or to suggest targets for rule-based reasoning. CBR may also be used for speedup in learning, with initial rule-based problem solving building up a case library that can then be used instead of rules, bypassing costly reasoning from scratch, or to avoid errors by storing exceptions to rules. Conversely, rule-based reasoning may be useful to augment the case library and extend the range of problems that a CBR system can solve.

CBR in the Large

A growing focus of CBR research concerns harnessing Internet-based knowledge sources. Such sources include formal ontologies, data sets available as linked open data, knowledge that can be mined from text in general-purpose unstructured Web sources such as Wikipedia, and the vast range of experiential knowledge now available on the Web. For example, databases of reviews provide a rich source of cases generated by many individuals, which could potentially be a source for CBR. More generally, stories are available in many forms, and contain rich case information.

An important enabler for applying CBR to unstructured Web sources is textual CBR, which aims at applying CBR processes to textual sources. Web-based sources are also being exploited for roles such as providing the knowledge needed to support case adaptation.

Another active focus is exploiting structured records of processes, as captured on the Internet and elsewhere, to generate structured cases. This has spurred interest in process-oriented CBR and trace-based reasoning, which examine how CBR can be applied to business workflows, e-Science provenance traces of scientific computing workflows, and other types of raw traces, to exploit episodic knowledge to support future tasks. For example, in e-Science, provenance capture tools have been developed to automatically capture traces of the derivations of data by scientific computing processes. The process information captured by provenance traces can be mined to generate cases, which become a source for CBR systems to use to aid nonexperts at constructing workflows for future experiments.

CBR Applications

Applications of CBR include both autonomous and interactive systems. As observed by Kolodner (1993), human users are often adept at evaluating the relevance of prior cases and applying their lessons, but may lack the experience needed to acquire a sufficient set of cases. On the other hand, case adaptation and evaluation are difficult for CBR systems, but practical methods exist for accessing large case libraries. These complementary strengths have led to increasing focus on case-based 'retrieve and propose' systems that support human reasoners by providing them with relevant prior cases to aid their decision making. For example, 'help desk' systems applying CCBR have been widely used to aid telephone support personnel who diagnose customer problems. Commercial CBR 'shells', which provide core CBR functionality for managing user-supplied cases, similarity information, and adaptation knowledge, are available to facilitate the development of such applications. As novel problems and solutions are added to the case base during use, a fielded CBR system builds up a sharable 'corporate memory' of cases, aiding corporate knowledge management. This has led to the use of CBR applications in many task areas.

Two illustrations of active CBR task domains are medical reasoning and electronic commerce. CBR has received attention in many medical reasoning contexts, for tasks such as diagnosis, decision support, interpretation of test results, and prescriptive systems to advise patients; bioinformatics applications are receiving growing attention as well. In electronic commerce, case-based support systems are used during online purchases of computers, to help buyers configure their systems by presenting similar past configurations as a starting point for them to modify. This helps users find products fitting their needs, even if initially they do not know all the important features to request.

In addition, the CBR cognitive model and CBR principles are guiding the design of educational systems by, for example, suggesting when useful learning is most likely to occur and how to retrieve examples to support that learning. Likewise, CBR is

being applied to accessing hypermedia and online repositories of information – providing indexing vocabularies and example-based query interfaces – and is being used to focus on information retrieval, in order to extract task-relevant information from large-scale information sources. Another active research area, textual CBR, develops methods for facilitating knowledge acquisition by automatically capturing and indexing cases in textual form.

Relationship to Other Artificial Intelligence Methods

Much artificial intelligence research focuses on methods for generating new solutions from scratch by chaining together general rules. CBR is based primarily on reasoning from specific experiences rather than general principles. In addition, learning is an integral part of CBR; much knowledge is acquired as a by-product of problem solving rather than precoded.

The learning done by CBR systems strikes a middle ground between knowledge-poor and knowledge-rich learning approaches. Unlike knowledge-poor inductive learning methods, CBR exploits domain knowledge when available. For example, many CBR systems use explanations to identify causally relevant features, guide indexing, and case adaptation. However, CBR does not depend on a complete and correct domain theory; unlike knowledge-rich methods such as explanation-based generalization, CBR can still be used in the absence of a rule-based domain theory.

In its emphasis on building up knowledge by learning, CBR research is in the same spirit as research on neural networks. However, CBR contrasts in storing and reasoning from examples rather than storing only learned generalizations. In addition, CBR performs 'lazy learning.' Rather than immediately generalizing training instances and discarding the examples, as in, for example, explanation-based and neural network learning, CBR stores cases with minimal processing and processes them further only if and when adaptation is needed to solve new problems. In addition, unlike neural networks, CBR systems can change behavior immediately in response to new examples: a single correct example of dealing with a situation, and no further training, is all that is needed for the system to process that situation correctly in the future.

Ian Watson observed that the use of a CBR approach does not require the use of any specific technology, but rather, requires the use of a reasoning process based on retrieval and adaptation of prior experiences, which may be realized in many different ways. For example, a CBR system could rely on a database system to store cases, and a rule-based system to adapt them.

Conclusion and References

A case-based problem solver solves new problems by retrieving stored problem cases and adapting their lessons to fit new circumstances; it learns by storing new episodes for future use. This process can provide robust reasoning and learning even in domains that are hard to codify in rule-based forms. As illustrated in the previous sections, CBR research has provided computational cognitive models of human information processing, artificial intelligence techniques, and the basis of information technology for a wide range of task domains.

The CBR cognitive model is discussed by Kolodner (1993) and Leake (1998). A volume edited by Leake (1996) begins with an introduction and tutorial, and then surveys the foundations of the field with chapters on classic issues and applications in tasks such as decision aiding, knowledge navigation, design, diagnosis, and education; Kolodner (1993) provides an in-depth examination of key issues; and a volume edited by Riesbeck and Schank (1989) includes chapters on important early CBR research projects and 'microversions' of the computer programs those projects developed. The process of developing CBR applications is described by Watson (2003). Mantaras et al. (2005) provide an extensive survey of numerous approaches to key CBR areas, as part of a journal special issue with commentaries on many facets of CBR (Aha et al., 2005).

Abstract

This article reviews what is known about how humans reason and how these processes underlie problem solving. The orthodox view was that deductive reasoning depends on formal rules akin to logic, but the evidence implies instead that it depends on mental simulation: individuals rely on mental models of the possibilities to which premises refer. This account applies to inductions of conclusions and to abductions of explanations. The three sorts of reasoning – deduction, induction, and abduction – underlie the solution of complex problems. But, problem solving can also demand creative insights, and the article concludes with an analysis of their nature.

Introduction

Psychologists have investigated reasoning and problem solving for over a century. Their studies of reasoning at first took for granted that reasoners relied on some sort of logic. Their studies of problem solving were scattershot investigations but began to be integrated in unified theories after the development of computer programing. This article begins with the psychology of the three main sorts of reasoning. In deduction, the aim is to draw a conclusion that must be true granted the truth of the premises, that is, to make a *valid* inference. In induction, the aim is to draw a plausible conclusion that goes beyond the given information, and so there is no guarantee of validity. In abduction, the aim is to induce an explanation of or hypothesis about the given information. Hence, abduction is a special case of induction, but one that aims to go beyond, say, a mere generalization of some facts in order to explain them. These three sorts of reasoning often underlie the solutions of problems, but problem solving may also depend on insights – a form of creative thinking. The article accordingly concludes with a description of how people solve problems.

Reasoning

Deduction

Problem 1: Either the fault is in the cable or the fault is in the software. The fault is not in the cable. So, what follows?

The answer depends on deductive reasoning, and the traditional arbiter of deduction is logic, which stipulates that an inference is *valid* if its conclusion is true in any case in which its premises are true. A valid solution to problem 1 is that the fault is in the software. Logicians distinguish between formal systems for deriving the proofs of inferences and semantic systems for establishing the validity of inferences. Sentential logic deals with inferences that hinge on sentential connectives, such as idealized versions of 'if,' 'or,' and 'and.' Its formal system can be framed using rules of inference for each of the connectives, for example:

- A or B.
- Not-A.
- Therefore, B.

The logical form of the premises in problem 1 matches this rule granted that *A* denotes 'the fault is in the cable, '*not-A* denotes its negation, and *B* denotes' the fault is in the software.' So, a single application of the rule allows us to derive the conclusion that the fault is in the software. In contrast, the semantic system for sentential logic makes use of truth tables, which display the truth of a proposition as a function of the truth or falsity of its constituent propositions. So, the truth table for *A* or *B*, or *both* is as follows:

A	*B*	*A or B, or both*
True	True	True
True	False	True
False	True	True
False	False	False

This meaning of disjunction is inclusive because it allows that if both *A* and *B* occur, the disjunction is true, as shown in the first row in the truth table. For an exclusive disjunction, *either A or else B, but not both*, the first row is false. The first premise of problem 1 corresponds to the truth table above. The second premise, however, states that the fault is not in the cable, *not-A*, and so this proposition eliminates the first two rows of the truth table. The only remaining row that is true is one in which the fault is in the software, *B*, and so the inference is valid: its conclusion is true in the only case in which the two premises are true. The same inference follows from the interpretation of the disjunction as exclusive. Of course, a complete account of the sentential calculus, which itself is only a part of logic, calls for much more than a rule for disjunction. But, the present account suffices to illustrate the difference between formal rules and semantics.

Psychologists have followed in the steps of logicians. At first, they developed theories depending on formal rules of inference, such as the rule for disjunction above (e.g., Rips, 1994). They argued that the difficulty of an inference depends on the number of steps in its proof, and so the preceding disjunctive inference should be easy because it can be carried out in a single step. But, they allowed that rules in the full set for logical inferences differed in the difficulty of

their application, and they had some success in fitting the theory to experimental data.

Could reasoning depend instead on a semantic approach akin to truth tables? At first sight, the answer seemed to be: no. The reason is illustrated in the example:

Problem 2: Either the fault is in the cable or it's in the software and it's in the printer. It's not in the cable. So, what follows?

The conclusion that the fault is in the software and it's in the printer is readily derived from the preceding formal rule given that this conjunction is mapped into *B*. In contrast, the truth table for the disjunction calls for eight rows, because each of its three simple propositions can be true or false. In general, each time a simple proposition is added to an inference the size of the corresponding truth table doubles. Yet, the inference does not double in difficulty, just as problem 2 is not twice as hard as problem 1.

During the last 30 years, an alternative semantic theory has been developed based on mental simulations (e.g., Byrne, 2005; Johnson-Laird, 1983, 2006). Its essence is that when people understand the meaning of an assertion, the interpretative system builds mental models of each of the main possibilities to which it refers. A conclusion that holds in all the models of the premises is necessary; a conclusion that holds in most of the models is probable – the theory extends to numerical probabilities, and a conclusion that holds in one of the models is at least possible. The inclusive disjunction in problem 1 has three mental models, which are shown in separate rows in this diagram:

fault in cable	
	fault in software
fault in cable	fault in software

Mental models are not made of words, which are used here for simplicity, but from representations of the world. As far as possible, these representations are 'iconic,' in the sense that their structure corresponds to the structure of what they represent. Most importantly, they represent only what is true unless explicit reference is made to what is false. One consequence is that the number of mental models does not double with each additional simple proposition in an inference, and so models are much more feasible than truth tables as a foundation for human reasoning.

Evidence tends to corroborate models as simulations on which naive reasoners rely, that is, those individuals who have not mastered logic. A simple prediction concerns the difference in reasoning between inclusive and exclusive disjunctions. The rule of inference above applies to both sorts of disjunction, and so formal theories do not predict that inferences based on them should differ in difficulty. In contrast, an inclusive disjunction has three mental models, whereas an exclusive disjunction has only two mental models. For example, the exclusive disjunction, *either the fault is in the cable or else it's in the software, but not both*, has only two mental models:

fault in cable	
	fault in software

Fewer models are less of a load on working memory, and so the theory predicts that problem 1 should be easier with exclusive disjunctions than with inclusive disjunctions. Experiments have corroborated this prediction (Johnson-Laird, 2006; Chapter 3).

The theory makes a more striking prediction: reasoners should make predictable errors in reasoning, because mental models represent only what is true. Such errors should occur when individuals evaluate whether several assertions can all be true at the same time, that is, whether they are consistent. This task relates to logic, because one method of proof is to add the negation of a conclusion to the premises and then to prove that the resulting set of assertions is inconsistent. Consider the following problem in which both disjunctions are exclusive:

Problem 3: Either the pie is on the table or else the cake is on the table. Either the pie isn't on the table or else the cake is on the table. Can both of these assertions be true at the same time?

Most individuals respond, 'yes,' because they assume that when the cake is on the table both assertions are true. After all, their respective mental models each has a model of this possibility. But, this compelling inference is an illusion. It occurs because models represent only what is true. If instead each model represents both what is true and what is false, then the first exclusive disjunction has these 'fully explicit' models of what is on the table:

pie	not-cake
not-pie	cake

This diagram uses 'not-cake' to represent that it is false that the cake is on the table. Likewise, the second exclusive disjunction has these fully explicit models of what is on the table:

not-pie	not-cake
pie	cake

For both disjunctions to be true at the same time, there needs to be a possibility that they have in common. But, as the fully explicit models show, no such possibility exists. Ergo, the two assertions cannot both be true at the same time.

The preceding illusory inference is just one of a whole swathe of different illusions depending on various sorts of connective. They occur both in drawing conclusions and in assessing consistency (for a review, see Johnson-Laird, 2006; Chapter 11). (A set of assertions is said to be consistent if, and only if, they can all be true at the same time.) These illusions are a litmus test for reasoners' use of mental models, because no other current theory of reasoning predicts their occurrence, and it is not easy to see how to extend theories based on formal rules of inference to predict them. At present, such theories rely on rules that are correct, and the introduction of incorrect rules, which would be needed to predict the illusions, would yield an inconsistent system. In the case of mental models, however, the illusions are

a consequence of their failure to represent what is false. For most inferences, this assumption is benign. Its surprising consequences emerge only for some inferences, and they were discovered in the output of a computer program implementing the theory.

Dual Systems of Reasoning

Many psychologists distinguish between a rapid intuitive system of reasoning and a slower deliberative system (e.g., Evans, 2007). Individuals differ in the degree to which they submit their intuitions to a deliberative test (see, e.g., Stanovich, 1999). The same dual-process account also applies to judgments (Kahneman, 2011). The model theory distinguishes between the computational power of the two systems: intuitions rely on a primitive system that can represent only a single mental model and that can carry out only a small finite number of operations, whereas deliberations depend on working memory, and so they can construct alternative models and carry out loops of operations on them until they exhaust the capacity of working memory. One sign of the use of intuitions occurs when people have to draw conclusions from pairs of premises, such as:

Problem 4: Some of the authors are bakers. Some of the bakers are caterers. What follows?

Inferences of this sort are known as syllogisms, and their logic was formulated first by Aristotle, the founder of Western logic. Twelve different psychological theories of syllogisms exist to explain systematic errors. One common error, for example, is to draw the conclusion for problem 4:

Some of the authors are caterers.

This conclusion might hold given the premises, but the inference isn't valid, because the bakers who are authors need not be the same bakers who are caterers. One appealing theory is that naïve individuals draw probable conclusions rather than valid conclusions (Oaksford and Chater, 2007). Other theories are based on formal rules of inference (Rips, 1994), and still others on various intuitive heuristics. A recent meta-analysis showed that none of these theories is satisfactory (Khemlani and Johnson-Laird, 2012). What is needed is a dual-process theory in which the intuitive system constructs a plausible model of a set of individuals, such as, for the premises above:

author	baker	caterer
author	baker	caterer
author		
	baker	
		caterer

Unlike the previous diagrams, this diagram represents a single mental model of five different individuals, and it embodies the heuristic that repeated terms, such as 'bakers,' refer to the same individuals. The model supports the common but erroneous conclusion that some of the authors are caterers. Those reasoners who deliberate about this conclusion may succeed in constructing an alternative model of the premises in which they separate the bakers who are authors from the bakers who are caterers, so the first two individuals in the preceding model become two individuals of this sort:

author	baker	
	baker	caterer

The resulting model refutes the intuitive conclusion and leads to the response that no definite conclusion about the relation between artists and caterers follows from the premises. This dual-process theory gives a satisfactory account of syllogistic reasoning.

Induction

Inductions are inferences that use knowledge or beliefs to go beyond the semantic information in the premises. Because knowledge and beliefs are fallible, inductions are invalid, though they can yield true conclusions. Some philosophers, such as Karl Popper, have argued that inductions play no role in science. But, clear cases to the contrary have occurred in astronomy, meteorology, and medicine. For example, Kepler's first law of planetary motion describes the orbits of the planets as ellipses with the sun at one of the two foci. He studied Tycho Brahe's observations of the positions of planets and induced his laws from them. Likewise, in daily life, everyone makes inductions.

A common misunderstanding, attributable to Aristotle, is that inductions lead from the particular to the general. But, they can also lead from one generalization to another; for example, A poodle's jaw is strong enough to bite through wire; therefore, a German shepherd's jaw is strong enough to bite through wire. Individuals who know that German shepherds are bigger and stronger than poodles are likely to accept this inference. Inductions can also lead to particular conclusions, for example, the master of *The Herald of Free Enterprise*, a car ferry, inferred that the bow doors had been closed when it left Zeebrugge in Belgium on March 6, 1987. In fact, they had not been closed, the sea rushed in, the vessel capsized, and over 100 people drowned. Inductions can be risky.

Here are two similar inferences:

Problem 5: If the client makes an order, then the goods are shipped. The goods are shipped. What follows?

Most people infer: The client made the order.

Problem 6: If the client makes an order, then the goods are shipped. The client makes an order. What follows?

Most people infer: The goods are shipped. A subtle difference between the two conclusions is that the first one is in the past tense, whereas the second one is in the present tense, which often refers to an event in the future, because English has no future tense. The difference in tense reflects the timing of the two events in the conditional: first, the client makes an order, and then the goods are shipped. Reasoners take the categorical premise in each inference to refer to the present, and so naturally an event that occurs

earlier is in the past, and an event that occurs later is in the future. They unconsciously choose the appropriate tense to refer to these timings.

The difference between the two inferences reflects what is known as 'modulation.' That is, the meanings of clauses, what they refer to, and knowledge can modulate the core meanings of sentential connectives. In logic, connectives have a fixed meaning; in language, they have core meanings corresponding to their meanings in logic, but modulation can alter these meanings. One effect is the temporal modulation that occurs in the preceding examples: knowledge can introduce various relations between events referred to in the clauses governed by the connective, and one such relation is a temporal order, which, in turn, can be reflected in a reasoner's choice of tense. Another effect is to block the construction of models of possibilities. Consider the disjunction: *Either she doesn't play a musical instrument or she doesn't play the piano*. The core meaning of an inclusive disjunction, *not-A or not-B*, refers to three possibilities: *not-A & not-B*, *not-A & B*, and *A & not-B*. But, the present disjunction refers only to two possibilities:

not-instrument	not-piano	(not-A & not-B)
instrument	not-piano	(A & not-B)

The model of the possibility:

not-instrument	piano	(not-A & B)

is blocked because if she plays the piano then of course she plays a musical instrument. In other words, the disjunction – rather unusually – yields the definite conclusion that she doesn't play the piano.

Knowledge and beliefs are fallible, and so the use of the present and past tenses in the earlier inferences is not deductively valid – the inferences are inductions. One corollary of modulation is that no general form of inference, such as *not-A or not-B*, *B*; therefore, *not-A*, is guaranteed to yield a valid deduction whatever the contents of *A* and *B*. Validity, therefore, has to be decided on a case-by-case basis. Inferences are valid not in virtue of their logical forms, which match rules of inference, but in virtue of their meanings. A variety of experiments have corroborated the occurrence of modulations that add relations and that block the construction of models of possibilities. Induction accordingly increases semantic information: it eliminates possibilities, either by adding elements to mental models or by blocking the construction of a mental model altogether.

Human reasoners have an inductive skill that far surpasses any known algorithm, whether based on mental models or formal rules. It is the ability to formulate explanations. If an induction yields a generalization or a scientific law, then scientists, in turn, may be able to explain it on the basis of more fundamental ideas. For instance, Einstein's general theory of relativity explained planetary orbits as a result of the sun's mass curving space–time. Following the nineteenth century logician, C.S. Peirce, inferences yielding hypotheses or explanations are known as 'abductions.'

Abduction

Abduction is a special case of induction. As an illustration consider the problem:

Problem 7: If a pilot falls from a plane without a parachute, the pilot dies. This pilot did not die, however. Why not?

In both the United States and East Asia, some individuals respond with a valid deduction: This pilot did not fall from a plane without a parachute. But, others respond with explanations, such as:

- The pilot fell into a deep snowdrift.
- The plane was on the ground.
- The pilot was already dead.

This propensity to formulate explanations is extraordinary. It seems to depend on mental simulations, but no one has been able to figure out quite how it is done. Humans can offer putative explanations for almost anything. The following problem is based on two sentences selected at random from separate stories also selected at random, but one word in the second sentence was changed – the opening noun was replaced with a pronoun referring back to the previous sentence:

Problem 8: Celia made her way to a shop that sold TV sets. She had recently had her ears pierced. What's going on?

Individuals readily provide such explanations as:

- Celia was getting reception in her earrings and wanted the TV shop to investigate.
- She wanted to see her new earrings on closed circuit TV.
- She had won a bet by having her ears pierced and was spending the money on a TV set.

Occasionally, reasoners are unable to formulate an explanation, and it happens more often when the two sentences do not refer to the same individual (see Johnson-Laird, 2006; Chapter 14).

Problem 9: If your friend has gone to get the car then she'll be back to pick you up in less than 10 min. Your friend has gone to get the car. But, she has not come back in 20 min. What do you infer?

Logic can tell you that there is an inconsistency, but it cannot tell you how to answer the question. And it does not imply that you should withdraw your conclusion that your friend will be back in 10 min even though she hasn't returned. Logic is 'monotonic,' that is, with each additional premise, further valid inferences can be made, and no additional premise ever calls for the withdrawal of a previous conclusion. In contrast, human reasoning is 'non-monotonic,' that is, when a beautiful conclusion collides with an ugly fact, individuals tend to retract the conclusion. Students of artificial intelligence have devised many systems of non-monotonic reasoning, but none of them offers a psychologically plausible answer to problem 9.

One answer going back to William James is that when individuals discover an inconsistency between the consequences of their beliefs and the facts, they should revise their beliefs in a minimal way to restore consistency. So, you should cease to believe that your friend has gone to get the car. But, if you found yourself in the circumstances of problem 9, you are much more likely to try to explain what has happened. Perhaps your friend had difficulty in starting the car, or perhaps she ran into a one-way system that forced her to make a long detour. If you can simulate a plausible explanation, then it will have the

side effect of leading you to abandon at least one of your beliefs. But, inconsistencies elicit explanations, not minimal changes to your beliefs, because explanations help you to decide what to do.

Evidence corroborates this account. Experiments have examined inconsistencies, such as:

Problem 10: If someone pulled the trigger, then the gun fired. Someone pulled the trigger, but the gun did not fire. Why not?

Participants responded with causal explanations that resolved the inconsistency, for example: *someone emptied the gun and there were no bullets in its chamber*. In a further study, participants assessed the probability of putative explanations for such inconsistencies. On each trial, they assessed the probabilities of a cause and its effect (as in the response above), the cause alone, the effect alone, and various control assertions. They ranked as the most probable explanation, a cause and its effect (Johnson-Laird, 2006). Because these conjunctions were ranked as more probable than their constituent propositions, the assessments violated the probability calculus – they are an instance of the 'conjunction' fallacy in which a conjunction is considered as more probable than one of its constituents (Kahneman, 2011). They show that the most plausible resolutions of inconsistencies are explanations, not minimal changes to beliefs.

Problem Solving

Problems are of many, many sorts. This article has already illustrated 10 different sorts of problems in reasoning. In fact, there are so many problems that, as the theory of computability shows, there are not enough solutions to go round, that is, many problems are provably insoluble (including the problem of determining whether or not a problem is soluble in principle). In science, mathematics, and technology, problems can be complex and unique, such as the problem of determining how cholera was transmitted from one person to another, the problem of breaking the Nazi Enigma code, and the problem of constructing a controllable heavier-than-air craft. A close examination of how individuals solved these particular problems shows that they relied on all three sorts of reasoning (Johnson-Laird, 2006). But, they also relied on other sorts of thinking, including analogies and creative insights (see Holyoak and Morrison, 2012).

Many sorts of problem are not unique but come in variations that each call for thought. To complete a tax form, for example, is a problem that most people have to solve over and over. When they first tackle such a problem, they may flail around trying one move and then another with only a few constraints, if any, governing their choices. With experience, however, they acquire a strategy for solving the class of problem, that is, a set of systematic constraints that guide their generation of elementary tactical moves leading to a solution.

A major advance in the psychology of problem solving occurred in Newell and Simon's theory, and its computer implementation (see Newell, 1990; Newell and Simon, 1972). In some cases, humans already know the strategy for solving a problem. Otherwise, they have to use weak strategies applicable to problems of many sorts. A natural strategy is to work forward from the initial state of a problem toward its solution, constrained by available knowledge. Another strategy, which goes back to Plato, is to start with the required solution and then to work backward toward the initial state. This strategy is known as 'means-ends' analysis because it depends on knowledge of the means available to achieve the ends. A problem solver assesses the difference between the current state of the solution and the required goal state. As long as there's a difference between the two, the solver searches for a move that reduces the difference. If no such move is available, the solver sets up a subgoal to find such a move, and means-ends analysis is applied recursively to this subgoal. The size of the space of possible sequences of moves – the 'problem space' – does not always predict the difficulty of a problem.

The means-ends strategy has been influential both in the study of how humans solve problems and in the development of hypotheses about the overall architecture of the mind (Newell, 1990). But, it is not applicable to certain problems, such as:

Problem 11: Given the following 6 squares, remove 5 pieces to leave exactly 3 squares with no loose ends, i.e., pieces that are not connected to any other piece at one or other end.

The goal is described, but not in the form of an explicit solution that allows a solver to compare it with the current state of the solution. What happens as individuals solve a series of such problems is that they gradually learn the different moves that can be made and deduce their consequences. One move is to remove the two pieces at right angles to each other that make up an external corner: the effect is to eliminate one square. Another move is to remove a single piece, such as the middle piece in the bottom row, which also eliminates one square. The removal of the two top corners and the piece in the middle of the bottom row solves the problem: five pieces are removed to leave three squares. With no experience of these problems, individuals tend to start out by trying out one move or another in a process of 'trial-and-error.' They generate a move and deduce its consequences. Even though the move may be futile and have to be undone later, they have learned something useful. A key assumption is that the problem-solving system can shift knowledge from the evaluative stage of the process to the generative stage. Hence, knowledge that individuals infer from deducing the consequences of a move can shift so that it starts to act as a local constraint on their generation of moves. With further experience, many individuals realize that a global constraint on each move in the problem is the current ratio of the number of pieces to be removed to the number of squares to be eliminated. They can then deduce the set of pertinent moves to be considered next, for example, if the ratio is much greater than one, then an appropriate move should, if possible, remove many pieces but only one square.

Another strategy in solving certain problems alternates between working forward and working backward. Individuals start working forward from the initial state and then switch to

working backward from the goal, especially if they get stuck. They alternate in this way until they either solve the problem or give up. A theoretical goal is to categorize all the feasible human strategies for solving problems. The difficulty is to take into account all possible sorts of problems (see Holyoak and Morrison, 2012; Part 4).

Insight

Sometimes when you are trying to solve a problem, you have a sudden insight and the solution pops into your mind seemingly from nowhere. When Archimedes was in the bath thinking about how to measure the volume of a king's crown, he suddenly realized – perhaps as he lay down and water slopped over the edge of the bath – that he could easily measure how much water the crown displaced. Legend has it that he cried, 'Eureka,' the Greek for 'I have it,' leapt from the bath, and ran naked down the street. When you have an insight, at one moment you are at an impasse unable to solve a problem, and at the next moment you are aware of the solution. Some sorts of problems depend on an insight for their solution whereas other sorts of problems do not. But, the occurrence of an insight is a subjective matter. It depends on whether an individual solved the problem, and on whether it was a result of a discontinuity in their thinking yielding a significant change of which they were aware.

Psychologists have studied problems whose solutions seem to depend on insights:

Problem 12: In the following simple addition, each letter has a unique value, and D = 5, so what are the values of the remaining letters?

```
  DONALD
+ GERALD
--------
  ROBERT
```

It follows at once that T = 0. Individuals can then try substituting different integers for letters using trial and error. But, this procedure soon leads nowhere: there are too many possibilities. As you study the problem, a sudden insight may hit you about the column: O + E = O. This pattern can occur only if E = 9, and there is a carry of 1 from the previous column. Such insights are essential to solve the problem.

Insight seems different from the normal process in which you make steady progress toward solving a problem. Skeptics doubt whether it depends on a special sort of thinking. If you search for the number that opens a combination lock, its discovery is bound to be sudden, but it does not depend on a process that differs from the one that hitherto failed. Experimental evidence, however, shows that insight is different (Holyoak and Morrison, 2012; Part 4). In routine problem solving, you have a sense that you are getting 'warmer' as you approach a solution. This sense does not occur prior to an insight. The difference is even evident in the regions of the brain that become active. So, what are the mental processes underlying an insight?

At least three hypotheses are plausible. The first is that individuals become fixated on an inappropriate method, but a period in which they think about other matters allows the misleading cues to wane, and so the insight – a switch to the correct cues – is more likely. Such perseverations certainly occur, but the problem with this hypothesis is its assumption that individuals know the correct method but can't access it. The claim may hold for some problems, but insights sometimes lead to the discovery of new methods. The second hypothesis, which is based on the idea of a problem space, is that insight depends on switching from a search in the current problem space to a search in the meta-level space of possible problem spaces for a new representation of the problem. In a case of insight, this new representation yields the solution to the problem. For example, most people are at first defeated by the problem of the 'mutilated' chessboard. The goal is to cover a chessboard with dominoes, or to prove that the task is impossible, but the board has been mutilated by the removal of a square at one corner and a square of the same color at the diagonally opposite corner. Individuals who start laying out dominoes on the board get nowhere. They have the wrong representation of the problem. The key insight depends on constructing a new representation: each domino covers one white square and one adjacent black square, but the diagonally opposite corners are of the same color. Hence, after they are removed, the remaining squares do not include equal numbers of black and white squares, and so the task is impossible.

A third hypothesis is that insight depends on a change in the constraints governing the problem-solving strategy. The current constraints yield an impasse. The abductive system registers the impasse, and so it sets up an attempt to modify the constraints. The process is initiated consciously, but it proceeds unconsciously. Modified constraints may, or may not, yield a solution. In the case of a false insight, you think that you have a solution, but, despite the change in constraints, you subsequently deduce that you were wrong. A genuine insight is accordingly an initial failure to solve a problem, followed by a change in constraints, followed by a solution. Once an insight has occurred, it may be used henceforth to constrain the generation of moves. A change in constraints is bound to be discontinuous, but it may be preceded by useless changes. A special case of a change in constraints yields a new representation of a problem. But, other insights depend merely on relaxing the existing constraints.

Abstract

Problem solving forms an essential part of daily intellectual activities, not only for adults but also for infants and young children. Planning, or the internal processes that mediate an intended action, is a crucial cognitive component for efficient problem solving, with its earliest precursor observed in infants below 1 year of age. This article reviews representative empirical research in the field, which involves various behavioral tasks including tool use such as spoons, tube problems, and maze tasks. Mental processes underlying these behaviors develop from simple prospection of events to organizing different event sequences to face novel problems.

Problem solving undoubtedly forms an essential part of our lives, not only for everyday events but even for more global and political problems. Psychologists have asked how developing humans become capable of problem solving. Traditionally, Jean Piaget suggested a renowned four-stage model of logical thinking, beginning with the sensorimotor stage at 0–2 years before proceeding to the preoperational, concrete operational, and formal operational stages toward adolescence (Piaget, 1985). Piaget's stage-based models and research methods, which largely depended on the linguistic reports of children, came to be criticized with the advent of the cognitive approach in the 1970s (Fujimura, 2011). That is, researchers have come to place greater emphasis on the internal processes underlying problem solving, which develop in continuous ways while involving multiple, mutually related mental systems.

Based on such cognitive perspectives, efficient solution of complex problems should be mediated by sophisticated forms of planning, which is deemed as the internal process of formulating an organized method about one's future behavior (Friedman and Scholnick, 1997; see also Friedman et al., 1987). Planning ahead should be beneficial for human infants and children, because it should enhance efficient decision making when the agent encounters various physical and social events. Literature on developmental psychology has suggested that planning ahead in order to achieve a goal is present during the second year of life, with its earliest precursor starting during the first year. Planning-based problem solving is deemed especially important in that it essentially involves storing information in the brain from the outer world and then internally transforming and organizing multiple elements of future actions in an appropriate sequence (Miyata and Fujita, 2011). Such active representational systems are regarded as a hallmark of human thinking. Humans' uniqueness in this respect appears relevant despite the fact that comparative cognition studies have recently insisted that even some nonhuman species, including primates and birds, may possess planning capabilities at a certain limited level (for an overview, see Emery and Clayton, 2004; Miyata and Fujita, 2011).

This article reviews representative literature on empirical research relevant to problem-solving capabilities in infants and young children. It especially focuses on how modern, cognitive perspectives understand problem solving at different developmental stages. Evidence from each stage is considered in terms of the levels and complexity of the underlying internal cognitive processes. Also raised are the issues that require elaborated work in future, including metacognitive processes and neural underpinnings of problem solving.

Prospective Control in Infants

Prospective control of motor behavior is found in very young infants, even though this process should be distinguished from problem solving. Even for infants less than 1 year of age, object properties such as size and orientation elicit preparatory sizing of grip and adjustments in hand orientation (Lockman et al., 1984; Newell et al., 1989; von Hofsten and Ronnqvist, 1988). A number of studies also suggest that these infants may be using mental imagery to guide motor behavior. Clifton et al. (1991) presented small and large objects in the dark, which elicited a one-handed grasp and two-handed grasps, respectively, to 6-month-olds. Before the testing, participants had been shown these objects in the light, which were paired with unique sounds. The infants successfully chose the appropriate grip configuration for each object's size. McCarty et al. (2001a) presented 9-year-old infants with rods oriented either vertically or horizontally out of the infant's reach, before making the room dark and bringing the rod within reach of the participant. Infants exhibited appropriate hand orientation for these invisible rods, in comparable ways as when the rods were visible. Both these studies suggest that infants made motor adjustments on the basis of the memory for the object they had seen earlier.

Another example comes from a moving object paradigm. von Hofsten (1980) presented infants with a moving toy whose trajectory brought it within reach of participants. Analyzing how infants reached out to grasp the toy, von Hofsten (1980) argued that infants anticipated the future point in space at which they would intercept the toy. Not only motor behaviors but also kinematic measures have suggested use of mental imagery when reaching invisible objects. Clifton et al. (1994)

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23074-2

presented 7-month-old infants with sounding objects in the dark and found that the moving speed of participants' hands decreased after approaching the object, in comparable ways as they do when reaching visible objects. This was suggested to reflect use of mental imagery regarding the object's location. These studies are suggestive, although not conclusive, that infants below 1 year of age may use some mental imagery about forthcoming events. However, these prospective behaviors are not likely to reflect problem solving guided by planning, which should involve active manipulation of internal representations to achieve a goal.

How do infants move from simple prospective behavior to planning-based performance? Planning in its simplest form should require at least two steps; that is, first reaching an object and then using the object that is in hand to achieve a certain goal. Motor adjustment during a goal-directed behavior would provide one key to this stage. Studies involving adults have contrasted reaching and grasping of an object when they performed subsequent divergent actions. Johnson-Frey et al. (2004) reported that approach kinematics in adults was influenced by the participants' intention to replace the object to a novel location, in contrast to simply holding and lifting the object. Marteniuk et al. (1987) showed that the adults' approach to an object was slower, had lower peak speed, and had a longer deceleration as the hand approached the object, when precise perceptual-motor action was subsequently required. Berthier et al. (1996) found that the same kinematic pattern was observed when approaching a small, delicate object, as opposed to a larger object. Do infants at a certain developmental stage show comparable goal-directed behavior? Claxton et al. (2003) presented 10-month-old infants with a ball and encouraged the participants to either throw it down or fit it into a hole. The latter case required a more precise and detailed action than the former. Both peak and average speed of the approach for the object was lower in the latter condition, suggesting that infants cognitively planned the subsequent action while approaching the ball by hand. Such motor adjustment could involve prospective control while looking beyond what is being seen and considering what to do after grasping the object, and thus could be a precursor of complex problem solving that appears at later stages.

Formulating Sequential Actions

Toddlers in the second year of life come to perform fairly complex, sequential actions. For example, they perform on simple maze and puzzle tasks (Miyata et al., 2009). At around 18–24 months of age, they come to build block towers (Bayley, 1969). At the beginning, they can balance just two or three blocks, but soon the number of blocks increase to five or even more to form a tall tower. Building a tall block tower requires precise sequential movements of picking up and stacking pieces of blocks. That is, it should involve cognitive abilities such as planning sequential actions, anticipating in advance the outcomes of these actions, as well as having a representation of the correct goal state. It also requires sufficient motor skill to put successive blocks on top of the tower. Parents are often impressed by both the cognitive capacities and motor skills achieved by the toddlers at this stage.

Chen et al. (2010) investigated individual differences in the motor skills when toddlers between 18 and 21 months of age built block towers, by examining the kinematic measures of their movements. They asked whether high-tower builders show speed profile when approaching the tower and releasing the blocks different from that of the low-tower builders. Toddlers were presented with two tasks: one was the precision task of performing tower building, while the other was the imprecise task of 'cleaning up' the blocks by placing them into a wide, open container. Point of peak velocity, which specifies the point during the movement at which the hand reached its fastest speed, was used as a kinematic measure showing individual differences in motor skills. Toddlers who built high towers reached peak speed earlier in their movements compared to those who built low towers. These patterns of reaching peak velocity early in the movements were comparable to data from adults (Berthier et al., 1996; Johonson-Frey et al., 2004). Retesting the same children when they are around 3 years old no longer replicated comparable individual differences, when all children had sufficiently mastered the task. These findings by Chen et al. (2010) appear important in that toddlers below 2 years of age show good capabilities for complex sequential planning and motor skills. However, the task still does not require hierarchical organization of multiple components or movements, as observed in the tool use contexts.

Development of Action Planning

Friedman and Scholnick (1997) described the sequence of problem solving as first representing the problem, then devising and carrying out a solution, monitoring its effectiveness, and finally making necessary corrections. This organized schema is true for young children's behaviors when learning to use a tool, such as picking up a spoon. McCarty et al. (1999) identified three grips when 9- to 19-month-old children grasped and used spoons and other toys. A radial grip occurred when the handle was grasped with the thumb toward the goal end of the item (i.e., the bowl of the spoon). An ulnar grip occurred if the handle was grasped with the thumb away from the goal end of the item. A goal-end grip occurred if the end of the item was directly grasped. The ulnar grip and the goal-end grip both indicate lack of planning, and the radial grip was deemed to be the only correct and efficient strategy suggesting action planning. Nine-month-olds persisted in primarily using their preferred hand, disregarding the orientation of the item. This resulted in the awkward ulnar or goal-end grips when the spoon was in the difficult orientation. The infants often incorrectly placed the handle of the spoon directly in the mouth. This tendency to reach with the preferred hand was also observed in the 14-month-olds. However, they made corrections when necessary, so that they placed only the bowl of the spoon in the mouth and never its handle. The 19-month-olds tended to inhibit reaching with their preferred hand. They alternated hands on the basis of the orientation of the spoon, reaching with their handle-side hand to achieve a radial grip. In this way, food could be transported efficiently and smoothly to the mouth.

Based on these findings, McCarty et al. (1999) proposed a model suggesting four action planning strategies used by children learning to pick up a spoon. The first is called the 'feedback-based strategy,' in which the child simply follows his or her own preferences until a situation occurs where the child can recognize that the goal has been achieved. The second is the 'partially planned strategy,' in which the child plans the transport of the spoon to the mouth, but does not control for the grasping strategies. The third is termed the 'fully planned strategy,' in which the orientation of the spoon is first taken into account, so that the child can grasp the handle of the spoon with an efficient, radial grip. The final stage is referred to as the 'habitual solution,' where grasping of the spoon with a radial grip has become a heuristic and no longer requires solution of a problem on every trial.

Interestingly, this developmental trend toward an efficient grip was observed only for the spoons and not for the other toys, such as rattles and bells. One interpretation could be that children may have recognized the consequence of their planned actions. That is, correct use of a spoon resulted in having food as reward, whereas the goals of grasping a toy seemed more diverse and undetermined. Another reason could be that the spoon had great familiarity and involved a self-directed, as opposed to other-directed, action. McCarty et al. (2001b) addressed the latter hypothesis by comparing the use of radial grips by 9- to 24-month-olds between different tools. Specifically, the hammer and the magnet involved other-directed actions, whereas the familiar spoon and the less familiar hairbrush could be either self-directed or other-directed. Results clearly revealed that, for both familiar and unfamiliar items, self-directed actions elicited more correct, radial grips than did the other-directed ones. Age difference was also found in that the older groups tended to use the radial grips more frequently than the younger groups. Claxton et al. (2009) further used a waterwheel task that involved both self- and other-directed actions, in which the salience of the outcomes between a radial grip and an ulnar grip was quite enhanced. Again, the self–other difference in planning the correct action was observed. These data suggest that self-directedness of the actions still plays a crucial role in terms of planning an efficient action strategy at the end of the second year.

To what extent does the progress to higher levels of action organization as observed for spoons effectively generalize to other situations? Chen and Siegler (2000) found that children around 2.5 years of age were able to select an appropriate rake among several ones differing in length, after which they successfully transferred this knowledge to new rakes when superficial aspects of their physical appearances were altered. On the other hand, Metevier (2006) showed that 36-month-old children had great difficulty in coordinating two different tasks in an appropriate sequence. That is, most children failed to use a rake to retrieve a rod and then to use that rod to expel the toy from a tube, even though they performed well on these separate problems. These data suggest that the efficiency with which children around 3 years of age can transform problem-solving strategies obtained in one task to wider domains differs greatly depending on factors such as self-directedness, task complexity, and so on.

Encouraging children's Problem Solving

An effective way to enhance problem solving for young children could be to give verbal or other instructions to encourage the use of efficient strategies. Adults are well capable of effectively using visual images to help solve a number of problems (Kosslyn, 1975; Wohldmann et al., 2007). Are comparable visualization techniques available for young children? Rieser et al. (1994) found that 3-year-old children were capable of using visual imagery to imagine spatial locations of objects in another room. Richards and Sanderson (1999) showed that children 3 years of age or older effectively used imagery when solving syllogistic reasoning problems. A more recent example comes from a 'gravity error' paradigm. In the original task, Hood (1995) used a tube problem in which children were asked to find a ball that was dropped into one of the three tubes. The tubes were all opaque and were sometimes interwoven to form a visuospatial maze. Three-year-old children made errors by consistently searching in the location directly beneath the point at which the ball was dropped. This was termed a gravity error, reflecting the children's erroneous assumption that an object should drop straight down from where they saw it disappear. Hood (1995) found that the gravity error was persistent even after attempting to train 3-year-olds on how to solve the problem. Joh et al. (2011) further devised verbal instructions when 3-year-olds solved comparable tube problems, by encouraging children to imagine the ball rolling down the opaque tube. Children given this instruction performed better than the control participants, who just waited without imagining the movements of the ball. This suggests that children used the experimenter's explicit encouragement by instructions to imagine the paths of the ball.

More direct instructions on how to solve the problem could also be helpful for children of these ages. Bascandziev and Harris (2010) used a tube paradigm comparable to Hood (1995), in which the experimenter gave verbal instructions on how the tube constrained the movement of the ball. Children were instructed to follow the tube with their eyes to its end, so that they could determine where the ball would reappear. Three-year-old children, although not 2-year-olds, successfully benefited from this instruction to improve searching performance. Even though eye movements of the children were not recorded, it appears plausible that 3-year-olds effectively scanned the apparatus with their eyes during the invisible displacement. The results thus suggest that these preschoolers are capable of using visual imagery when solving physical problems and that the use of more sophisticated visualization strategies could be enhanced by adults giving effective testimony or encouragement. These emerging mental capacities should be the crucial keys that later leads to more complex planning and problem solving during childhood, which is to be integrated into more abstract representational systems and executive functions.

Higher Stages of Complex Problem Solving

Internal processes underlying problem solving during the preschool ages move from simple action or event planning to more organized and structured mental strategies to face the

complex world. Hudson and Fivush (1991) proposed four levels in the development of event planning at this stage. Level 0: simple anticipation of a sequence of actions for familiar events; level 1: single goal event planning, or the process of mentally considering different options for the sequence of actions to achieve a single goal; level 2: multiple event goal planning, or taking into account alternatives for sequential actions having two or more goals in mind; level 3: coordinated event planning, or mentally decomposing event sequences into multiple subgoals and hierarchically organizing subgoals from different events; level 4: novel event planning, or decomposing event sequences into multiple actions and subgoals, then modifying and joining these components to construct novel action sequences. These different levels imply that children become better aware of the relationships between actions and goals, while using the goal state to construct more complex plans.

Hudson et al. (1995) examined the ability of 3-, 4-, and 5-year-old children to construct plans about familiar events such as going to the beach and going grocery shopping, by analyzing the verbal reports of participants. They showed that these children are capable of constructing advance plans, that is, representation of an expected sequence of actions planned in advance of an action. The researchers further found that the ability to construct more complex plans – such as remedy plans, that is, plans to remedy unexpected mishaps that may occur in the process of carrying out advance plans, and prevention plans, that is, advance plans that include actions intended to prevent mishaps from occurring – develop with age. Hudson et al. (1995) suggested that 3- and 4-year-olds' plans would have reflected level 1: single goal event planning, such that they could at most use knowledge about familiar events to anticipate event sequences. By contrast, 5-year-olds were suggested to exhibit level 2: multiple event goal planning, and level 3: coordinated event planning, such that these children could now flexibly adapt their plans to achieve novel goals.

Can these developmental courses be observed not only for verbal problems but also for nonverbal cognitive tasks? To consider this issue, maze tasks should provide one fine example. Detour or maze problems have been used frequently in development psychology. Piaget (1954) traditionally argued that infants toward the end of the sensorimotor stage become capable of taking indirect routes that go beyond direct perception of the disappeared object during three-dimensional detour navigation. Lockman (1984) showed that infants made reaching detours before corresponding locomotor detours, and that they were less likely to make detours around transparent than opaque obstacle barriers. Diamond (1990) suggested that infants in the latter half of their first year start to employ detour reaches to retrieve objects placed in a transparent box with an opening to one side.

What about maze navigation in young children? Miyata et al. (2009) examined the performance of 3- to 4-year-old children on computerized maze problems by using a touch-sensitive screen. These mazes were based on a navigation task originally developed to test pigeons' (*Columba livia*) maze-solving performance and planning (Miyata et al., 2006), to move a target square to a goal square by making sequential responses on the touch monitor with fingers. In the first experiment, children around the age of 3 years were proficient at making a detour to reach the goal while avoiding an L-shaped barrier. Participants took direct routes more frequently than indirect routes. In the second experiment, a plus-shaped maze task was used, and the goal occasionally jumped to the end of another corner when the target arrived at the center of the maze. Parallel to pigeons (Miyata and Fujita, 2008), the 3- and 4-year-old children exhibited both correct responses toward a new goal and errors toward the old goal location immediately after the goal shift, with reaction times longer when they made correct responses than when they made errors. In addition, 3-year-olds had greater difficulty immediately adjusting their previously planned strategies after the change of goal locations, whereas 4-year-olds more frequently adjusted their response toward a new goal. This seems consistent with the use of higher level plans such as remedy plans and prevention plans as the children become older, testified by using a rigid nonverbal behavioral paradigm. More recently, Miyata and colleagues modified the computer-assisted navigation task so that it required 3- to 5-year-old children to visit two or three identical goals in a sequence, a task that represented a traveling salesperson problem (unpublished data). Preliminary analyses suggested that older children used more efficient route selection strategies by shortening the overall lengths of the traveling paths, consistently with the development in the levels of planning.

Future Perspectives

We have so far seen how primitive forms of prospective control during infancy subsequently lead to action planning, which then becomes more sequential and organized during early childhood to attain flexible problem-solving performance. Modern cognitive perspectives collectively have drawn decent sketch on the developmental course of mental systems underlying problem solving, whereas future research may involve a number of promising issues that still remain to be explored. One topic to be covered concerns the development of metacognition involved in problem solving. Frese and Stewart (1984), for example, regarded metacognitive planning as the most sophisticated among different levels of planning, in terms of the degree of abstraction. According to Frese and Stewart (1984), a metacognitive plan entails the person's knowledge of general problem-solving strategies, which should enable the person to generate novel plans in any area. Despite the assumed large adaptive value of this capability when facing novel situations, little empirical work so far has addressed its developmental course. For example, before starting to solve a problem, one could determine whether or not to start the plan if one has metacognition on whether he or she knows the solution to it. This could be examined by analyzing whether hint-seeking behavior is more frequent before solving difficult problems than before solving easy ones (Miyata and Fujita, 2011). Not just verbal reports by children but also more systematic, computerized settings could be effectively used to examine nonverbal metacognitive processes.

Another important perspective for future work concerns the neural correlates of problem solving in infants and young children, the issue relevant to the emerging field of cognitive developmental neuroscience. A number of neuroimaging techniques including functional magnetic resonance imaging and positron emission tomography, which require immobilization

during testing, have been difficult to be applied to infants and young children. However, recent progress in near-infrared spectroscopy (NIRS) has enabled measurement of brain activities in infants younger than 1 year (Minagawa-Kawai et al., 2008). NIRS noninvasively measures changes in hemoglobin concentration and its oxygenation level accompanying regional brain activities, by emitting and detecting continuous near-infrared lasers with two wavelengths. It also enables measurement of cortical activities in live situations of problem solving. For example, Miyata et al. (2011) applied the plus-shaped maze task comparable to Miyata et al. (2009) to adult humans using NIRS. In addition to large prefrontal activities during maze performance, right inferior prefrontal cortex also showed significant activations after making error responses, suggesting use of additional cognitive resources for adjustment of movements. Application of these behavioral paradigms to infants and young children using NIRS should promisingly uncover differentiated brain activities associated with different stages of planning and problem solving. Efforts inspired by these emerging perspectives should help to draw novel and more sophisticated pictures on the developmental course of problem solving, in a way that could be effectively connected to a broader literature on humans' cognitive development.

Procrastination

Piers Steel, Haskayne School of Business, University of Calgary, Calgary, AB, Canada
Katrin B Klingsieck, Faculty for Arts and Humanities, University of Paderborn, Paderborn, Germany

Abstract

Procrastination is a pervasive and pathological delay, where we put off despite expecting to be worse off. It is associated with other forms of self-regulatory failure, rooted in our neurobiology, though can be exacerbated by environmental features. Though several effective treatments for it are available, procrastination is self-perpetuating as procrastinators will often focus on emotional coping strategies, putting off dealing with the source of their delays.

Part 1. Definition and Types of Procrastination

Terms and references that can be ascribed to procrastination occur throughout the historical record, dating back to ancient Egypt's middle of the 18th dynasty, under the reign of Thutmosis III (i.e., "Friend, stop putting off work and allow us to go home in good time"). It appears in most major religious texts, including Islam, Hinduism, Buddhism, and Christianity. It is also increasingly common, with approximately 25% of the modern population confessing that they typically procrastinate. Given its prevalence, it is unsurprising that the term has been used in various ways to describe different forms of delay. However, among all these descriptions, common themes do emerge.

Definitions of Procrastination

Procrastination is typically taken as an irrational or a self-defeating delay, to be worse off for putting off. After a historical review of definitional efforts, Steel (2007) integrates previously established key components to produce, "to voluntarily delay an intended course of action despite expecting to be worse off for the delay." Further building on this effort, Klingsieck (2013a) refines this definition to, "the voluntary delay of an intended and necessary and/or [personally] important activity, despite expecting potential negative 3 procrastinated, it should be: i) intended, ii) voluntarily delayed, iii) foreseeably pathological." However, there is tension among all these components as they all can be considered continuous dimensions. An 'intended' task may range from a flippant notion to a proclaimed goal. Circumstances may make goal pursuit easy, meaning any delay is clearly voluntarily, to extremely difficult verging on the impossible, making delay effectively involuntary. The problematic consequences of the delay can range from the obvious to the unapparent in both likelihood and magnitude. Though there are some delays that are clearly procrastination and some that are not, it can be debated when one becomes the other.

Differences between Procrastination and Strategic Delay

Procrastination requires delay but is not equivalent to delay. However, at times the notion of 'active' or 'positive' procrastination will arise, referring to a strategic self-serving delay (Chu and Choi, 2005). This is not compatible with the dominant use of the term or procrastination's strong association with self-regulatory failure. However, there are forms of positive or purposeful delay that superficially appear similar to procrastination. In particular, purposely leaving a manageable portion of a project until near the deadline, taking advantage of increased motivation that occurs then, can be beneficial. In contrast, involuntarily leaving excessive amounts of work until just before the deadline because one cannot find motivation earlier typically is not. In the former, the person can choose to work earlier but prefers not to. In the latter, the person may prefer to work earlier but cannot find the motivation. Helping to differentiate the two is the question "How useful would it be for you to have more motivation earlier, well before the deadline?." While everyone might find more motivation desirable, for the procrastinator this will be especially so.

Types of Procrastination

Typologies of procrastination can be organized by life domain (e.g., academic or health), by self-reported reason or justification (e.g., rebellion or arousal), and by cause (e.g., self-efficacy or value driven). Since procrastination appears to require some sort of impulsive weakness of the will, where we act against our own best interests, it is facilitated by proximity to temptations or environmental cues. Personality traits are predictive of what temptations procrastinators tend to be susceptible to, resulting in different phenomenologies of procrastination (Schouwenburg, 2004). People high in the personality trait of extraversion, for example, will ascribe their procrastination to their need to socialize while conversely those low in extraversion (i.e., introverts) will attribute their procrastination to their need for solitude. Most studied among these is the neurotic or perfectionist procrastinator, who is most likely to seek clinical treatment and has given rise to the belief that perfectionism causes procrastination in general. Though there is almost no association between perfectionism and procrastination, impulsive perfectionists should personally experience their perfectionism as being the cause of their procrastination and this particular typology may respond well to techniques for managing anxiety.

Demographic Differences

Though procrastination is found within all societies and all time periods, there are areas of prevalence (Steel and Ferrari, 2013). To begin with, it is associated with a modernized society as greater access to temptation increases the incident rates of procrastination. Sensibly, the easier and more enjoyable it is to put off tasks, the more people procrastinate. Cultural values also may influence the rate of procrastination among nations, with Ireland reporting the most procrastination among English-speaking countries. Procrastination, being self-defeating, is associated with lower levels of income and education and less relationship success. In short, procrastinators are more likely to be unemployed, less educated, and single. Finally, procrastination is seen more in men than women and in the younger rather than older. Notably, sex differences in procrastination partially explain women's rise both academically and in the workforce.

Part 2. Measurement of Procrastination

As per the definition of procrastination, there are certain inherent problems in identifying when procrastination occurs. It may not be entirely clear to the observer or even the individual. The degree of intentionality of the task is not always evident and possibly malleable in retrospect. Obstacles may intervene hindering speedy completion of the task that are as seen insurmountable by the individual but only inconvenient by an observer. Also, the consequences of the delay may not be evident, allowing the overly optimistic, who truly believes there is plenty of time left, to appear to be a procrastinator to a dispassionate observer. Finally, standards and desires differ so the exact same consequences for delay can be procrastination by one, who is worse off, but not for another (Silver and Sabini, 1981).

Self-Report

Procrastination, like personality measures, can be measured as an overall general trait or by specific life domain. Typically, improved measurement can be achieved by using as specific a measure as the context will allow. By 2006, there have been at least 10 procrastination measures used in research (Steel, 2007), with several more developed since.

General Measures

Among the most popular of the general measures of procrastination are the General Procrastination Scale (GPS), the Adult Inventory of Procrastination (AIP), Tuckman Procrastination Scale, and the Decisional Procrastination Scale (DPS). Notably, the first three of this list is often characterized as representing behavioral procrastination, the delay of a task, while the last of these represents decisional procrastination, the delay of choice. While there is support for goal choice and goal pursuit to represent distinct stages, the DPS does show strong associations with the other behavioral measures and even contains an item "Even after I make a decision I delay acting upon it." It is questionable whether the decision procrastination, as measured, is a separate construct.

More recently, there appears to be criterion contamination problems among many of these measures (Steel, 2010). They assess procrastination by not only asking if the person delay irrational (e.g., "Putting off until the last minute has cost me money in the past"), but also if the person is prompt (e.g., "I generally return phone calls promptly") or if the person simply delays (e.g., "I find myself running later than I would like to be"). While the last two components are related to procrastination, they are not procrastination itself. Failing to be prompt is not the same as procrastinating and simply being busy or overcommitted can cause delay.

In response, the Pure Procrastination Scale has been developed that focuses purely on irrational delays, comprised of items from the DPS, the GPS, and the AIP that load together and reflect the traditional definition of procrastination (Steel, 2010). It shows improved associations with key outcome variables, such as subjective well-being, and proves to be functionally equivalent to the Irrational Procrastination Scale, which is designed to assess procrastination as an irrational delay.

Specific Measures

With life domains ranging from the marital to the financial, there are numerous potential ways to focus procrastination. Though some other specific measures have been used, such as procrastination regarding household safety, only one area has proven dominant: academic. In particular, Solomon and Rothblum's (1984) seminal measure, the Procrastination Assessment Scale – Student is often employed in this context, though somewhat basic in construction. It asks students to rate 'school activities in general' as well as five specific tasks (e.g., writing a term paper, keeping up with weekly readings) in term of how much they procrastinate, whether their procrastination is a problem, and do they want to stop procrastinating. In addition, there is a separate 'reasons for procrastination scale,' which provides 26 possible explanations for student's procrastination.

Given that procrastination is equally or even more of concern in many other life domains, including financial, such as failing to put enough aside for retirement, and health, such as failing to seek treatment, more specific measures for other domains should be entertained.

Observed

Difficulties in observing procrastination have not prevented several attempts. To the extent that the outcome of delay is clearly foreseeable, adverse, and there is task commitment, observed measures of procrastination are likely valid, especially in the aggregate. Like self-report measures, academia has proven to be of particular interest.

Academic Measures

Difficulties in observing procrastination are assuaged somewhat in an academic setting. Goals can be assigned, such as quizzes or essays, ensuring that a majority of students have a degree of intention. Problems of procrastination are well known in this setting and early starts are repeatedly counseled. The effect of delay is foreseeable and adverse, at least in many cases. Consequently, academic self-reports of procrastination and observed delays in this context are substantively associated (Steel et al., 2001). Specific

assignments typically used include the following: class attendance, course grade, quiz grade, and meeting a deadline for an assignment. Other less common academic aspects assessed include getting a PhD, publication rate, getting tenure, and timing of experimental participation. In particular, a computerized personal system of instruction, often now used in massive open online courses, provides an almost ideal venue to study academic procrastination. The pace of assignment completion, which is among the best inconspicuous measures of observed procrastination, can be automatically assessed for an extremely large number of people. Using this as a measurement foundation, a comprehensive set of interventions and diagnostics can be explored.

Other Measures

Other attempts to assess procrastination behavioral are far more limited. Interesting examples include when Christmas shopping is done, a gift receipt or check is cashed, or a letter is mailed. To some extent, an open critique is that the delay may not be irrational but due to the participant simply being busy or uninterested. One exception to this is by Reuben et al. (2007), who gave MBA students the option of either cashing a smaller check now or a larger check later. Though most students choose the smaller but immediate check, they did not cash it until after they would have received the larger but later one.

Looking forward, more success may be achieved by creating observed or behavioral measure at the group, neighborhood, or nation level. It would be constructed by identifying common, foreseeable, and almost universally beneficial tasks required for most people. For example, this may include the degree they pay their bills on time, the number of canceled dentist appointments, the degree of preparation for retirement, or the ratio of gym memberships to gym attendance. While individual exceptions to these self-regulatory tasks may occur, especially if there are financial constraints, in aggregate it would reveal if a community was indeed prone to procrastination.

Self-Deception

Because procrastination has ambiguous aspects, it leaves the possibility for self-deception. We can retrospectively recast our behavior as unintentional (e.g., "I wasn't really planning to do that anyway"), as unforeseeable (e.g., "I thought I had enough time!"), or as beneficial (e.g., "It is probably best I didn't get that done"). This can be considered an emotional coping strategy, where people look for explanations that are pleasing or self-serving (Sirois and Pychyl, 2013). This strategy is common in impulse-related disorders, where people sacrifice larger but later benefits for short-term rewards. Consequently, procrastinators may tend to congregate and compare themselves to other procrastinators to facilitate downward counterfactuals, where we contrast our situation with those even worse off. Denial, aside from making procrastination difficult to assess, also perpetuates the condition. Taking a task-oriented strategy, rather than an emotional coping strategy, tends to reduce the degree of procrastination. At times, procrastinators must accept and forgive themselves for their procrastination before they can move from an emotional to a task-oriented coping style (Wohl et al., 2010).

Part 3. Research Perspectives

Concerning the field of psychology, theoretical approaches to procrastination can be grouped into several perspectives (Klingsieck, 2013a). These perspectives are differential psychology, the perspective of motivational and volitional psychology, the perspective of clinical psychology, the situational perspective, and the perspective of neurobiology.

Perspective of Differential Psychology

Differential psychology understands procrastination as a personality trait. Studies in this perspective have built up an extensive nomological network of procrastination and have focused on studying the relationship of procrastination with other trait and traitlike variables (Klingsieck, 2013a).

The Big Five

The big five is a common personality taxonomy used to study procrastination (Steel, 2007; van Eerde, 2003). Increased procrastination is mainly associated with decreased conscientiousness while the factors of extraversion, openness to experience, and agreeableness are not significantly related to procrastination. Neuroticism has an intermittent relationship with procrastination, depending on the measure, which disappears once conscientiousness is controlled for. In addition, some studies have examined the relationship between intelligence and procrastination, but have found no correlation (cf Steel, 2007).

Perfectionism

Early works in the field viewed procrastination as primarily caused by irrational beliefs, such as perfectionism (Burka and Yuen, 2008). Correlational results do not support this notion, indicating a relatively minor contribution compared to other constructs, especially self-efficacy and impulsiveness. However, the role of perfectionism continues to be debated. One reason for the mixed results might be the different approaches to operationalize perfectionism. Within some articles it is understood as a one-dimensional construct, while other authors understand perfectionism as a multidimensional construct (e.g., procrastination associated with socially prescribed perfectionism vs procrastination associated with self-oriented perfectionism). Alternatively, perfectionism's perceived relationship may be due to an increased likelihood of neurotic procrastinators seeking treatment – a self-selection effect – combined with any other major personality trait, high or low, will be experienced by an individual as being instrumental in causing their procrastination (Schouwenburg, 2004). However, this does not preclude that treating pathological perfectionism beliefs could help the *neurotic* procrastinator.

Self, Self-Esteem, and Self-Handicapping

Procrastination is also related to low self-esteem and certain identity aspects such as a diffuse ego identity and greater discrepancies between actual, ought, and desired self. Whether this is a cause or consequence of procrastination is debatable. To the extent that low self-esteem is related to low self-efficacy, it can be viewed as a cause. To the extent that low esteem is due to the compromised performance resulting from procrastination, it is an effect. On balance, the mostly widely

adopted position in the procrastination field is the former of these, that it is a cause, especially with regards to self-handicapping. Delaying tasks until it becomes difficult to determine a person's true capability can be a self-esteem protecting strategy. On the other hand, it can be argued that self-handicapping is a more calculated act and does not reflect the impulse-driven behavior typically associated with procrastination. In either case, they both represent self-defeating delays, but may respond to different treatments. Self-handicappers would best be treated by challenging underlying irrational beliefs. Procrastinators would best be treated by reducing the preference reversal effects of impulsiveness.

Time, Time Orientation, and Time Preferences

Concerning time-related personality styles, procrastination is associated with circadian rhythms known as the 'eveningness' type (Digdon and Howell, 2008). With regard to time orientations, procrastinators seem to display a reduced focus on the future, a fatalistic focus on the present (only avoidance procrastination) or a hedonistic focus on the present (only arousal procrastination), and negative attitudes about the past (Jackson et al., 2003).

Perspective of Motivational and Volitional Psychology

The motivational and volitional psychology perspective understands procrastination as a failure in motivation and/or volition (Klingsieck, 2013a), leading to the intention–action gap (Steel, 2007).

Motivational Aspects

Concerning motivational aspects, procrastination is less likely to occur in the case of intrinsically, self-determined, or flow-inducing activities. Furthermore, low procrastination is related to a mastery goal orientation and internal locus of control. Self-efficacy is often studied with regard to academic procrastination. However, studies display mixed results concerning the role of self-efficacy. Some studies understand and investigate test and self-efficacy as individual contributors to procrastination, while others focus on the mediating role of self-efficacy between perfectionism and procrastination. However, meta-analytically it has on average a strong connection (Steel, 2007).

Behavioral Economics and Temporal Motivation Theory

The phenomenon of procrastination violates the mainstream economic assumption of rationality, being a purposeful and self-defeating delay. Consequently, the field of behavioral economics, which relaxes the rationality assumption, has shown more interest in the phenomenon. Typically, economists adopt a version of the behavioral psychology's matching law, which has similarities to classical economics' subjective expected utility equation, except that rewards are hyperbolically discounted. The concept of hyperbolic discounting or time discounting allows for an interdisciplinary bridge between psychology and economics in the explanation of procrastination. Within this realm, procrastination is related to picoeconomics and the rational choice framework, as well as the concept of present-biased preferences.

The Temporal Motivation Theory (Steel and König, 2006) explains procrastination from a time-discounting perspective. It is an integrative theory that incorporates the best-validated aspects of the core motivational theories. Results were that the constructs of expectancy (e.g., self-efficacy), value (e.g., task aversiveness), and time sensitivity (e.g., impulsiveness) are the major predictors of procrastination. These constructs are organized into an equation consistent with other major theories, particularly Expected Utility Theory, Hyperbolic Discounting, and the Matching Law. Mathematically expressed, $\text{motivation} = (\text{expectancy} \times \text{value})/(1 + \text{impulsiveness} \times \text{delay})$. Motivation increases as the expectancy of an outcome and the size or value of an outcome increase. Motivation decreases as the delay before this outcome and the impulsiveness increases. As per Figure 1, procrastination occurs due to preference reversal, where a proximally or immediately available temptation pulls or distracts away from a former intention. According to this theory, procrastination is more likely to occur if the outcome of an unpleasant activity offers rewards in the distant future.

Volitional Aspects

Concerning volitional aspects, procrastination is associated with decreased self-regulation, decreased self-control, decreased action control, or volitional problems in general. More specifically, procrastinators seem to lack time management strategies, seem to be easily distracted by attractive action opportunities, and display a less frequent use of learning strategies.

Perspective of Clinical Psychology

The clinical psychology perspective focuses on the conditions of and interventions for the clinically relevant extent of procrastination (Klingsieck, 2013a). In explaining procrastination, these theoretical approaches often draw on psychoanalysis, cognitive behaviorism, and neuropsychology (for a summary, see Steel, 2012). Of all the perspectives, it is the clinical one that puts the negative consequences and correlates of procrastination intensely into focus because these determine whether procrastination is clinically relevant or not.

Affective and Cognitive Aspects: Fear of Failure, Test Anxiety, and Depression

Self-help books often state that the most prominent causes of procrastination are irrational beliefs, such as fear of failure or

Figure 1 Preference reversal due to temporal discounting.

test anxiety. Thus, procrastination is often investigated within a framework of coping styles and anxiety (e.g., Burka and Yuen, 2008).

Depression is considered both a cause (through the mechanism of diminished energy) and a consequence (through the mechanism of reduced performance) of severe procrastination. However, procrastination is related to depression only for clients diagnosed with depression, being that procrastination is a symptom of the condition.

Behavioral Aspects: ADHD

In realm of procrastination's link to impulsiveness, the relationship between procrastination and attention deficit hyperactivity disorder (ADHD) is discussed but rarely studied. The Axis 1 disorder ADHD is identified by procrastination among other symptoms, such as inattentiveness, difficulty in getting work done, and organizational problems. However, like depression, procrastination is related to ADHD only for persons diagnosed with ADHD, it being a symptom of the condition. For individuals who are not diagnosed with ADHD, procrastination is not associated with attention deficits. However, procrastinators are more likely to be prone to boredom than nonprocrastinators and, like those with ADHD, seek more stimulating situations (Ferrari, 2010).

Situational Perspective

Although intuitively obvious, especially given the volitional problems of procrastinators, few studies have been conducted that focus on environment characteristics that promote procrastination. Thus, the situational perspective encompasses only a small subset of theoretical ideas and empirical studies on procrastination. The situational perspective understands procrastination as a phenomenon that is evoked by certain environmental characteristics (Klingsieck, 2013a). The features associated with procrastination are task difficulty and attractiveness, plausibility of the assignment, autonomy, teachers' or supervisors' characteristics, and the proximity and saliency of temptations and distractions.

Perspective of Neurobiology

Research endeavors in the field of neurobiology have been scarce, although the dualistic theory of mind provides a promising model to explain procrastination (cf Steel, 2012). Referred to by various terms, such as hot/cool, passion/reason, or system 1/system 2, it indicates that the prefrontal cortex often makes or maintains intentions. However, when the mechanisms of the prefrontal cortex are exhausted or compromised, decision making relocates to the limbic system. The limbic system is much more susceptible to short-term temptations and distractions. Consequently, we make intentions to act but find it difficult to follow through despite wishing we would. Drawing on historical records, functional magnetic resonance image research, genetic studies, comparative psychology, developmental psychology, and evolutionary psychology, Steel (2012) finds considerable support for this model. There is also empirical evidence that procrastination can be largely explained by problems with the prefrontal cortex role as the executive function (Rabin et al., 2011).

Part 4. Impact in Different Life Domains

Procrastination research has investigated procrastination in a variety of different life domains, however, studies that compare procrastination's characteristics across different domains are yet to be conducted (Klingsieck, 2013a; for a first endeavor see Klingsieck, 2013b). The life domains studied are education (i.e., academic procrastination), work and financial, health, and subjective well-being. Each of them is briefly discussed below.

The procrastination of study-related activities in a student population is often studied under the term academic procrastination. While procrastination also focuses on procrastination in other life domains, this domain is the most studied within procrastination research. The research mainly focuses on reasons and consequences of procrastination showing that procrastination can have a detrimental impact on achievement and on subjective well-being of students.

Research on procrastination with regard to job-related aspects has concentrated on procrastination of job search behaviors and workplace performance. Procrastination has been shown to be negatively related to implementation intention formation, but to positively predict intention–behavior discrepancies and the extent to which job seekers engage in other activities instead of performing planned job search activities. Moreover, it is also negatively related to the process quality of job seeking. Research concerning procrastination in the workplace is surprisingly scarce. This is striking given that Steel (2012) reviews estimates that put procrastination at over 25% of most people's work time, potentially reducing productivity by $1.25 trillion in the United States alone. Studies have included identifying what job characteristics exacerbate procrastination (i.e., the situational perspective) as well as the consequences of procrastination. For instance, procrastination is frowned upon in the workplace. Interestingly, although procrastination is often understood as a deficit in self-management, it does not seem to be related to deficits in managing others. Concerning the procrastination of important financial aspects, studies have shown that the majority of people by their own standards feel that they have procrastinated savings for their retirement too long. The same holds true for procrastinating on taxes.

The health domain is one of the more procrastination relevant area, speaking to the speed of seeking treatment or 'patient compliance' in treatment programs. Constructs studied in the health domain are often the same as for academic procrastination (e.g., self-efficacy, self-control), indicating that this is largely the same phenomenon and the results are transferable. Within the health area, procrastination presents itself as a self-regulation deficit leading to the intention–action gap with regard to dieting, physical training, and preventive medical checkups. For example, colon cancer is among the deadliest despite being the most treatable, simply because people delay getting colonoscopies.

Procrastination has been shown to have various negative effects on subjective well-being. For example, it has been shown to result in augmented stress and regret. Procrastinators often report having feelings of personal failure due to their procrastination and frustration regarding their inability to start earlier. Furthermore, studies have shown that procrastination can also pertain to enjoyable activities, where people put off pleasurable pursuits. Although procrastination might function

as a short-term mood repair, in the long run it has negative consequences on subjective well-being.

Part 5. Treatments

The negative consequences of procrastination have led to the development of various intervention programs and to the publication of numerous self-help books to overcome procrastination. One of the oldest treatment ideas is the idea of behavior control. Most interventions have focused on either teaching self-management strategies (e.g., goal setting, time management, planning, monitoring, creating the right environment for studying) or implementing therapeutic strategies to tackle negative affect and cognitions (e.g., cognitive restructuring).

The number of these self-help books concerning procrastination has grown steadily in recent years. The works written by counseling psychologists emphasize irrational beliefs, such as perfectionism and low self-esteem, by procrastinators (e.g., Burka and Yuen, 2008). The works written by research psychologists (e.g., Ferrari, 2010; Steel, 2012) indicate that procrastination is primarily a self-regulation failure and an impulse-related issue. Consequently, they focus on improving self-regulation skills and situational or stimulus control.

Therapeutic strategies in overcoming procrastination pertain to techniques of cognitive restructuring (to tackle negative cognitions), relaxation exercise (to tackle negative affect), time restriction, and, paradoxical interventions. For example, a special issue of the *Journal of Rational-Emotive & Cognitive-Behavior Therapy* (REBT; Dryden, 2012) came out in which different approaches concerning REBT are delineated. Anxiety-based treatments are likely to be most effective for the perfectionist or neurotic procrastinator. On the other hand, the outpatient clinic at the University of Münster (Germany) has built a special outpatient clinic for procrastinators focusing on cognitive-behavioral therapy that may be more broadly applicable. The methods they employ include realistic goal setting, stimulus control, and self-motivation.

Most trainings aiming at overcoming procrastination foster strategies concerning self-management such as goal setting, time management, planning, monitoring, and creating the right environment for studying. For a summary of these interventions, see Schouwenburg et al. (2004).

Procrustes Analysis

John C Gower, The Open University, Milton Keynes, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Procrustes analysis is concerned with matching two or more configurations. It has its origins in factor analysis, where the problem is to match configurations that represent different sets of factor loadings. More recent applications are concerned with matching multidimensional configurations arising from forms of multidimensional scaling or from direct measurement. Emphasis is on matching the shapes of the configurations independently of their position. Orthogonal rotations are commonly used, but more general transformations may be allowed. When simultaneously matching several configurations, their average configuration gives an important summary, analogous to the group-average of individual differences scaling and some forms of generalized canonical correlation.

Procrustes analysis is concerned with matching two, or more, configurations of points. Imagine two maps of a region, each giving the positions of the same towns. The two maps are oriented differently, are of different sizes, differ in their accuracies, and use different map projections. At first glance, it may be difficult to see much resemblance between the two maps. Procrustes analysis addresses such problems, usually taking one of the configurations as a target and fitting the other to it, optimally, by using appropriate transformations. The 'maps' may be derived in many ways and may be in several dimensions but, for the concept of matching to be meaningful, it is important that the configurations refer to two representations of the same things: the same towns, the same cases (in multidimensional scaling (MDS)), the same variables (in factor analysis), the same products (in marketing), and the same landmarks (describing biological organisms).

The name comes from Greek mythology where Procrustes was an innkeeper who had a bed (sometimes two). Travelers were stretched or limbs chopped to make them fit the bed; with two, adjustment was ensured. The pejorative implications are no worse in Procrustes analysis than in other forms of data analysis, where, misguidedly, data may be fitted into the straightjacket of an unrealistic model.

Factor Analysis

The origins of Procrustes analysis (see Hurley and Catell, 1962) are in factor analysis, where loadings $\mathbf{X}_1$ of k factors $\mathbf{f}$ occur in the form $\mathbf{X}_1\mathbf{f}$ and so may be replaced by $(\mathbf{X}_1\mathbf{T})(\mathbf{T}^{-1}\mathbf{f})$, showing that they are determined only up to the arbitrary $k\times k$ matrix $\mathbf{T}$. By choosing a suitable $\mathbf{T}$, we may match $\mathbf{X}_1$ 'the traveler' to a previously determined or hypothetical set of loadings given in a matrix $\mathbf{X}_2$ 'the bed'; $\mathbf{T}$ representing the chopping/stretching transformation. Usually, the degree of match is judged by least squares, minimizing $\|\mathbf{X}_1\mathbf{T}–\mathbf{X}_2\|$ the sum of the squared distances between like points of the target and transformed configurations. Without further constraint, this is the multivariate multiple-regression problem with well-known solution.

$$\mathbf{T} = (\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1'\mathbf{X}_2$$

Two of the most important constraints on $\mathbf{T}$ are

1. $\mathbf{T}$ must be orthogonal (denoted here by $\mathbf{T}=\mathbf{Q}$) and
2. $\mathbf{T}$ must be a direction cosine matrix (denoted here by $\mathbf{T}=\mathbf{C}$)

Both choices relate to the interpretation that $\mathbf{f}$ is expressed relative to its orthogonal system of coordinate axes and the columns of $\mathbf{T}$ give direction cosines of new axes relative to the original orthogonal axes. When $\mathbf{T}=\mathbf{Q}$, a new set of orthogonal axes is being sought that gives a better match to $\mathbf{X}_2$; when $\mathbf{T}=\mathbf{C}$ we imagine $\mathbf{X}_2$ as being referred to oblique axes. The orthogonal Procrustes least-squares solution is $\mathbf{Q}=\mathbf{V}\mathbf{U}'$. where $\mathbf{U}\boldsymbol{\Sigma}\mathbf{V}'$ is the singular value decomposition of $\mathbf{X}_2'\mathbf{X}_1$. With $\mathbf{C}$, minimization is intrinsically more difficult and is less well defined than in the orthogonal case. This is because there are at least two ways of expressing the position of a point relative to oblique axes and also because there are good arguments for replacing ordinary least squares by a weighted form that measures distance in the metric appropriate to the chosen system of oblique axes, giving four variants in which $\mathbf{T}$ is either $\mathbf{C}$, $\mathbf{C}'$, $\mathbf{C}^{-1}$, or $(\mathbf{C}')^{-1}$. The simplest case was first discussed by Mosier (1939) but not finally solved until Browne (1967) gave a practical numerical method for solving the normal equations. Special algorithms have been proposed by Browne and Kristof (1969) and Gruvaeus (1970) for the case $\mathbf{T}=\mathbf{C}^{-1}$. However, all problems may be tackled uniformly by proceeding as if the directions of all but one of the axes are known and then estimating the optimal direction of the remaining axes, cycling through all the axes iteratively until a stable solution is found for all the directions.

Rather than handling the indeterminacy of factor loading as above, the modern tendency is to use an internal criterion of simple structure such as Varimax (Kaiser, 1958) that has no reference to an external target $\mathbf{X}_2$. Alternatively, $\mathbf{X}_2$ may be coded in binary form where $x_{ij}=1$ indicates a desired high loading of i the variable on the jth factor, and $x_{ij}=0$ indicates a low loading. This latter form remains a type of Procrustes problem, but least squares is no longer appropriate and is replaced by choosing $\mathbf{T}$ to maximize the ratio of the sum of squares of the squared high loadings to the sum of squares of the low loadings (see Lawley and Maxwell, 1971).

Variants and Later Developments

The problems outlined above are referred to as two-sets Procrustes problems because two configuration matrices $\mathbf{X}_1$ and $\mathbf{X}_2$ are involved. There are many variants:

1. Alternative constraints on $\mathbf{T}$ such that $\mathbf{T}$ is a rectangular column-orthonormal matrix, or is a permutation matrix
2. Two transformation matrices $\|\mathbf{X}_1\mathbf{T}_1–\mathbf{X}_2\mathbf{T}_2\|$
3. Isotropic scaling: minimize $\|\rho\mathbf{X}_1\mathbf{T}–\mathbf{X}_2\|$
4. Anisotropic scaling: minimize $\|\mathbf{X}_1\mathbf{S}_R\mathbf{T}–\mathbf{X}_2\|$, or $\|\mathbf{X}_1\mathbf{T}\mathbf{S}_R–\mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\mathbf{T}–\mathbf{X}_2\|$, $\|\mathbf{S}_L\mathbf{X}_1\mathbf{S}_R\mathbf{T}–\mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\ \mathbf{T}\mathbf{S}_R–\mathbf{X}_2\|$, or $\|\mathbf{S}_L\mathbf{X}_1\mathbf{S}_{R_1}\mathbf{T}\mathbf{S}_{R_2} - \mathbf{X}_2\|$ for unknown diagonal $\mathbf{S}_R$ and $\mathbf{S}_L$ where the suffices R and L denote whether the scaling matrices occur on the right or left of $\mathbf{X}_1$
5. Replace least squares by, e.g., L_1-norm, inner product of trace$(\mathbf{X}_2'\mathbf{X}_1\mathbf{T})$ or a robust estimation criterion
6. Two-sided Procrustes problems $\|\mathbf{R}\mathbf{X}_1\mathbf{T}_1–\mathbf{X}_2\|$ where $\mathbf{R}$ and $\mathbf{T}$ are to be estimated, usually under specified constraints
7. Weighted forms – minimize trace $\mathbf{N}(\mathbf{X}_1\mathbf{T}–\mathbf{X}_2)\mathbf{W}(\mathbf{X}_1\mathbf{T}–\mathbf{X}_2)'$ where $\mathbf{N}$ and $\mathbf{W}$ are given matrices, one of which may be ignored
8. Handling missing values

Brief comments on the above must suffice; Gower and Dijksterhuis (2004) give details. It should be clear that $\mathbf{X}_1$ and $\mathbf{X}_2$ no longer represent factor loadings. Anisotropic scaling allows for differences in size; the more esoteric versions of anisotropic scaling verge on the more pejorative interpretations of the Procrustes legend: permitting real violence to the data. The product of two orthogonal transformation matrices is equivalent to one and the inner product and least-squares criteria, then, give the same result. Weights $\mathbf{N}$ are useful to cover replication or missing rows of $\mathbf{X}_1$ and need not be diagonal, although they usually are. Note that weights are given matrices, whereas anisotropic scaling is expressed in terms of unknown diagonal matrices requiring estimation. However, sometimes $\mathbf{W}$ may be a function of the unknown $\mathbf{T}$, as with oblique Procrustes analysis in a metric where $\mathbf{W}$ is $\mathbf{C}'\mathbf{C}$ or its inverse. Albers and Gower, 2010 give an overview of the many complications that can arise when estimating missing values in Procrustes analysis.

Changes in orientation are given by an orthogonal matrix $\mathbf{Q}$, which includes rotations and reflections, leaving intact the essential distance and angular properties of the configurations. A $p\times q$ orthonormal matrix $\mathbf{T} = \mathbf{P}$ with q columns represents a projective from p to q dimensions. Projections may be interesting because

1. $\mathbf{X}_2$ has fewer dimensions than $\mathbf{X}_1$
2. A match may be required in some specific number of dimensions, say $q = 2$

When $q < p$ we may still match in p dimensions by rotating in the higher dimensional space; e.g., we may rotate three points lying on a line to fit three points lying in a plane. All we have to do is to augment $\mathbf{X}_2$ by $p < q$ zero columns. That $\|\mathbf{X}_1\mathbf{P}–\mathbf{X}_2\|$ can be less than $\|\mathbf{X}_1\mathbf{Q}–\mathbf{X}_2\|$ (where $\mathbf{X}_2$ is augmented by zero columns) has been seen as a justification for preferring projections to rotations, but this is not comparing like with like. I believe that projection Procrustes analysis is rarely justified.

Nowadays, applications of Procrustes analysis are more often than not more to do with matching configurations rather than factor loadings (Commandeur, 1991). For example $\mathbf{X}_1$ and $\mathbf{X}_2$ may be the two sets of points given by different MDSs of the same data, or they may refer to MDS solutions based on different proximity/distance matrices measured between the same p objects, perhaps based on different variables. Fruitful applications have been found in the food sciences, where $\mathbf{X}_1$ and $\mathbf{X}_2$ are derived from scores given by two judges on traits of several products (e.g., Dijksterhuis and Gower 1991/1992). Applications in the biological sciences include the analysis of shape where the configurations refer to the directly observed coordinates of landmark features on organisms (see e.g., Bookstein, 1991, Dryden and Mardia, 1998). In shape analysis the matching of one configuration to another is often termed registration.

Generalizations

Given K configurations $\mathbf{X}_1, \mathbf{X}_2, \mathbf{X}_3, \ldots, \mathbf{X}_K$ we may match them in pairs by doing the corresponding two sets of Procrustes analyses, minimizing $s_{ij} = \|\mathbf{X}_1\mathbf{T}_1–\mathbf{X}_2\mathbf{T}_2\|$ for all pairs (i,j). Each s_{ij} may then be assigned to a matrix $\mathbf{S}$ and analyzed by some form of MDS (see Gower, 1971 for an example from physical anthropology).

Alternatively, we may minimize $\sum_{k=1}^{K}\|\mathbf{X}_k\mathbf{T}_k - \mathbf{G}\|$ or $\sum_{k\leq k'}^{K}\|\mathbf{T}_k'\mathbf{X}_k'\mathbf{X}_{k'}\mathbf{T}_{k'}\|$ where $\mathrm{G} = \frac{1}{K}\sum_{k=1}^{K}\mathbf{X}_i\mathbf{T}_i$ often termed the group average. For the orthogonality criterion, both are equivalent to minimizing $\sum_{k=1}^{K}\|\mathbf{T}_k'\mathbf{X}_k'\mathbf{G}\|$. Generalized Procrustes analysis may be viewed as a three-mode analysis, with modes for rows, columns, and configurations (see Kroonenberg, 2008 for three-mode analysis). For some information on algorithms, see Ten Berge (1977). To help interpretation, each dimension of the analysis may be summarized in an analysis of variance, partitioning the total into terms for the group average and for departures from the group average. Some dimensions may be identified with noise and some with signal, further subdivided into displayed and undisplayed parts (Dijksterhuis and Gower 1991/1992).

It has been suggested that maximizing the group average of Procrustes analysis should be a main objective of Procrustes analysis. For orthogonal $\mathbf{T}$, both approaches are equivalent, but for projections, maximizing the group average is not the same as minimizing the criteria given above. The situation gets very convoluted, especially when the variants listed in Section 2 are admitted. This is because when focusing on the group average, the transformations, isotropic scaling, and anisotropic scaling may be regarded as being attached to $\mathbf{G}$ rather than to the $\mathbf{X}_i$, giving two versions of every variant (see Gower and Dijksterhuis, 2004 for further details).

The reason for focusing on maximizing the group average may be influenced by the important part played by the concept of a group average in several psychometric methods (see, e.g., Individual Differences Scaling) as a useful summary of K data sets. Ultimately, the range of such methods may be so divergent from orthodox Procrustes procedures that the Procrustes terminology becomes questionable. However, here we shall single out mention of generalized canonical correlation analysis, both

because of its superficial resemblance to Procrustes analysis and because of its general importance. There are several ways of generalizing canonical correlation analysis, but one of the most useful is based on the equivalent Procrustean forms $\sum_{k=1}^{K}\|\mathbf{X}_k\mathbf{T}_k - \mathbf{G}\|$ or $\sum_{k\leq k'}^{K}\|\mathbf{T}_k'\mathbf{X}_k'\mathbf{X}_{k'}\mathbf{T}_{k'}\|$, where now $\mathbf{T}_k$ is a general matrix whose columns conform with the rows of $\mathbf{X}_k$ but where $\mathbf{T}_k$ has r columns independently of k. Now the columns of $\mathbf{X}_k$ are interpreted as variables and not as coordinates of configurations. When $K=2$, minimization coincides with classical two-sets canonical correlation analysis, thus satisfying one of the primary conditions for generalization. The generalization to $K>2$ satisfies the generalized (two-sided) eigenvector problem. The columns of $\mathbf{X}_k\mathbf{T}_k$ are the canonical variables, and the Procrustean form of the least-squares criterion shows that the mean (i.e., the form taken by the group average) of the K canonical variables in each dimension matches the group average. The sum of squares of the correlations between the K leading canonical variables and the group average have a correlational interpretation, so linking the generalization with two-group canonical correlation.

The block matrix with elements $\mathbf{Z}=\{\mathbf{X}_k'\mathbf{X}_{k'}\}$, central to generalizing canonical correlation analysis, is also the basis of the STATIS method, usually after some initial standardization of each $\mathbf{X}_k$. The leading eigenvector of the matrix with (k,k')th element trace$\|\mathbf{X}_k'\mathbf{X}_{k'}\|$ estimates isotropic scaling factors s_k, say; then $\sum_{k=1}^{K} s_k\mathbf{X}_k$ may be interpreted as a group average. This and similar links between Procrustes analysis and other methods that involve a group average, are likely to be a continuing area for research in the immediate future. Research relating to biological landmark data and shape analysis remains active and will continue (see Kendall et al., 1999). Other research will focus on algorithms, the effects of estimation criteria and the difficult area of inference.

Abstract

Environmental sustainability is one of the most pressing issues facing societies today. Employees play a key role in contributing to organizational environmental performance. This article describes the domain of employee green behaviors (pro-environmental behaviors at work), distinguishes them from related constructs, provides an overview of determinants, and reviews interventions designed to support them.

Environmental problems are escalating. Research from scientific disciplines converges on the conclusion that the degradation of our natural environment has hastened and that the capability of natural systems to cope with such decline has been compromised (IPCC, 2013, 2014). Globally, societies are becoming increasingly aware of the negative consequences of environmental degradation on human health, ecosystems, and sustainability of life on earth.

Environmental sustainability, defined as "living within the regenerative capacity of the biosphere" (Wackernagel et al., 2002: p. 9266), must be one of society's most important goals in order to ensure the long-term viability of humanity on this planet. Two approaches to achieving environmental sustainability are mitigating current environmental harm and adapting human activities to function within the limits of the natural environment to limit future damage to the biosphere.

Economic activity has the largest impact on natural resources depletion, water use, land use, greenhouse gas emissions, and biodiversity loss. Businesses contribute to, but are also affected by, environmental degradation, which introduces uncertainty into supply chains and core business operations. In addition, consumers are demanding environmentally responsible business practices and products. Thus, business organizations, especially large multinational corporations, are increasingly concerned with understanding and contributing to environmental sustainability. Ultimately, organizations recognize that the viability of their continued operation depends on practicing *corporate social responsibility* and embracing a 'triple bottom line' that acknowledges the importance of social equity and environmental sustainability in addition to economic prosperity.

It is important to note that while corporate social responsibility (CSR) and corporate environmental performance are related, these two aspects of organizational performance are conceptually distinct, have different goals, and derive from distinct antecedents and interventions. CSR aims to improve the well-being of people directly (e.g., through charitable donations, safe working conditions, or by providing training and education). Environmental performance focuses on ensuring the sustainability of the natural environment, in order to protect *all future life* on this planet, by responsibly using natural resources. This theoretical distinction is especially important when managing employees, as the knowledge, skills, and motivation needed to support organizational, social, and environmental goals differ dramatically. Moreover, CSR and corporate environmental performance show different relationships with other variables such as corporate financial performance (Orlitzky et al., 2003).

For organizations, environmental sustainability means responsible management of natural resources in their operations, to sustain the natural environment for organizational economic viability, as well as present and future life on earth. According to a current survey of more than 1600 CEOs, resource scarcity and climate change are among the top five trends that are transforming business today (SAM and PwC, 2011). The same survey also found high CEO support for (1) protecting the interests of future generations (76%) and (2) measuring and reducing organizations' environmental footprints (80%). However, both goals are sufficiently broad to prompt a closer look at what business organizations are actually doing to support their environmental sustainability goals.

Organizational Pro-Environmental Initiatives

One prominent way that organizations support environmental sustainability is by enacting and implementing *organizational pro-environmental initiatives*, which refer to organizational level programs, actions, and interventions that enhance environmental sustainability. Functionally, they can be directed at minimizing, mitigating, and neutralizing environmental impact or at bringing about positive environmental change. Nearly all large organizations are implementing pro-environmental initiatives to some degree, and companies which are environmental leaders have implemented several dozen initiatives and embedded environmental sustainability into their core organizational identities and business strategies (Bansal and Roth, 2000).

Most proposed solutions to emerging environmental threats, including most organizational pro-environmental initiatives, are structural and material changes, such as the creation of new sustainable products, processes, practices, and technologies to replace ecologically harmful ones. Such advances are being made, but environmental scholars agree that the rate is slower than necessary to curb further damage. Organizations are also recognizing that slow to emerge technological and structural solutions to environmental crises

are unlikely to sufficiently protect their current and near-future economic interests. Environmental degradation can be considered a form of maladaptive human behavior (Maloney and Ward, 1973). Organizations do not consume resources, generate waste, or release pollutants. Such decisions are made, acted on, and demanded by leaders, employees, and consumers. Conversely, organizations do not behave in ways that promote sustainability, whereas individual employees do. Preventing and reversing environmental harm thus must involve changing unsustainable human behavior in general. In organizational settings, environmental sustainability goals are achievable only through the efforts of employees at all levels of the organization (Dilchert and Ones, 2012a).

Using Human Resources to Enable and Support Organizational Environmental Sustainability

Despite the key role that employees play in bringing about environmental outcomes, the impact of individual-level behaviors on environmental sustainability has been primarily examined in household settings (Dilchert and Ones, 2012b). The environmental contributions individuals make in their work lives may be more important because, through their actions, employees can impact the environmental performance of organizations as a whole. Hough and Muschewske (2012) astutely observed that "major innovations leading to increased levels of environmental sustainability will come from an engaged and committed workforce responding to a compelling vision communicated by business leaders that new ways to achieve shareholder value through improved environmental sustainability methodologies must be found." Employees are the building blocks on which organizational environmental performance is founded.

Individual Pro-Environmental Behaviors

The general domain of individual behaviors that contribute to environmental sustainability is referred to as *pro-environmental behaviors*, which have been defined as "individual behaviors contributing to environmental sustainability (such as limiting energy consumption, avoiding waste, recycling, and environmental activism)" (Mesmer-Magnus et al., 2012: p. 160). These behaviors may be public (for example, taking mass transit, participating in a rally for an environmental cause) or private (for example, composting, not using home air conditioning on a hot day). The positive environmental behaviors individuals engage in as part of their personal lives are volitional actions rooted in their own initiative. Although societal structures, such as the presence of a public transportation system or recycling program in one's city, may support or hinder pro-environmental behaviors, acting in ways that benefit the environment is ultimately a personal choice.

When environmental behaviors are performed in work organizations or as part of performance in individuals' work roles, they have been referred to as *employee green behaviors*. Employee green behaviors are defined as "scalable actions and behaviors that employees engage in that are linked with and contribute to or detract from environmental sustainability" (Ones and Dilchert, 2012a: p. 87). Besides the setting in which they take place (at work), these employee green behaviors are also distinguished from general pro-environmental behaviors by the degree of control that organizations exert over them. Whereas pro-environmental behaviors are wholly based on individual volitional choice, employee green behaviors are under greater scrutiny by the employer and might even be required by organizations as part of individuals' job duties. Their primary target of impact is the environmental performance of the organization.

In one regard, employee green behaviors are a more comprehensive concept, because – analogous to other performance constructs (see below) – they are defined to include behaviors with both a positive and negative impact on the natural environment. That is, positive employee green behaviors improve organizational environmental performance, whereas negative employee green behaviors detract from organizational environmental performance. Refraining from positive environmental behaviors is not the same as actively harming the environment. The former can be thought of as 'green behavior inhibition' and the latter as 'ungreen behavior activation.' Overall then, the definition of employee green behaviors distinguishes the concept from that of general pro-environmental behavior in terms of (1) organizational control over the behaviors, (2) their target (organizational environmental performance), and (3) their spectrum (positive/negative behavioral activation/inhibition). Although it would be fitting to refer to the domain as pro-environmental behaviors at work, we prefer the term employee green behaviors to highlight its distinctiveness from pro-environmental behavior more generally defined. When employee green behaviors are used as partial index of the employee's relative worth to the organization, they may be referred to as *employee environmental performance*.

The content and targets of employee green behaviors have been studied in a wide variety of organizations, jobs, and countries by researchers at the University of Minnesota and the City University of New York (Ones and Dilchert, 2012a; 2013). Critical incidents studies and careful consideration of several thousand specific behaviors were used to identify 16 broad types of employee green behaviors. These fall into five even broader main content categories. These categories, called the Green Five, are:

1. *Conserving*. This category includes behaviors aimed at avoiding waste and preserving resources. That is, conservation by reducing use, reusing, recycling, and repurposing resources is the behavioral content of this category. Frugality and thrift form the category's functional core.
2. *Avoiding harm*. This category includes behaviors aimed at reducing impact and mitigating environmental damage. Central to this category are behaviors that prevent pollution (or, at the negative pole, actions that pollute the environment). This category also includes monitoring one's environmental impact or footprint and taking steps to recover or restore the environment after damage has been done (such as planting trees, picking up litter, or cleaning an oil spill). The psychological core of most avoiding harm behaviors

(at the positive end) may be characterized by cautiousness, self-control, and responsibility.

3. *Transforming*. This category involves adapting and changing to be more sustainable. It includes creating innovative solutions, such as changing how work is done to be more sustainable and creating new sustainable products and processes, as well as adopting innovations made by others, such as choosing responsible alternatives (e.g., green products, renewable energy, durable materials) and embracing technologies that are better for the environment. Adaptability and openness to change are core to transforming behaviors.
4. *Influencing others*. This category includes social behaviors that support or enable other individuals' sustainable behaviors. It includes providing individuals with education and training to develop the knowledge and skills necessary to perform employee green behaviors. This category also includes behaviors that motivate, encourage, or support green behaviors, such as providing incentives for recycling, coordinating a carpool system, or praising individuals who come up with new green ideas. Leadership, sociability, and altruism are important in influencing behaviors.
5. *Taking initiative*. This category involves behaviors that break the mold or reject the status quo. In performing these behaviors, a level of personal risk is accepted to advance environmental sustainability. This category includes initiating new environmental programs or policies, lobbying and activism for the environment, and putting environmental interests first. Entrepreneurship, risk-taking, and self-sacrifice are hallmarks of these behaviors.

The behaviors within each of these categories are similar in the kinds of actions individuals take and in their psychological foundations, even if they are targeted at different sustainability goals or utilize different resources. For example, reducing water use, reducing energy use, and reducing food waste are all conserving behaviors involving the preservation of resources. These behaviors are psychologically more similar to each other than are reducing energy use, purchasing solar power, and designing a more energy efficient LED (behaviors all involving energy, but requiring divergent behavioral categories of conserving and transforming). Even though the behaviors in the second set are all targeted toward energy, the psychological mechanisms that impel them are quite different. When conceptualizing, measuring, and influencing employee green behaviors, it is important to acknowledge the multitude of behaviors that can contribute to a particular sustainability goal and that multiple targets can be affected through the same intervention.

Jobs and Pro-Environmental Behaviors

As economic activities evolve to incorporate capital and technological resources to address environmental sustainability needs of societies, labor demands also evolve. Embedding pro-environmental behaviors into jobs requires an understanding of job performance dimensions. Job performance is a multidimensional construct with a substantive general factor that spans across its higher order dimensions of task performance, organizational citizenship performance, and avoidance of counterproductive work behaviors (CWB; Viswesvaran and Ones, 2000). Rather than conceptualizing employee green behaviors as yet another performance dimension, we argue that environmental performance at the employee level can in fact span all of these dimensions. The degree to which such behaviors are considered task performance, citizenship performance, or counterproductive behaviors depends on their direction (positive/negative), target, and the nature of employees' job family and formal job duties.

Green jobs refer to new and emerging occupations that arise to address environmental sustainability needs, particularly in the energy production industry (e.g., wind turbine technician). For these jobs, job performance includes green task performance as part of task performance, green citizenship behaviors as part of citizenship performance, and the avoidance of environmentally harmful behaviors or green CWB. Thus, in these jobs, employee green behaviors span across all three general performance dimensions.

Greening jobs refer to occupations for which enhancements to skills are required to meet new sustainability-related demands (e.g., architects who need to acquire knowledge and skills for designing energy efficient buildings). For these jobs, green task performance demands are increased in level and/or variety. Citizenship behaviors directed at environmental sustainability and avoidance of CWB in the sustainability arena are also conceptualized as part of job performance.

Greening economy jobs are traditional occupations for which demand is increasing to meet expanding green industry needs as economies are undergoing environmental sustainability transformations (e.g., clerical workers in recycling companies). For these jobs, no (or few) components of task performance are expected to focus on green task performance. However, there may be increased demand on employees to perform green citizenship behaviors and avoid green CWB, given green organizational focus and concerns.

Finally, even for occupations that are not part of these taxonomic categories, the economic and cultural milieu of organizations focused on the triple bottom line mean that employee green behaviors increasingly are included as part of individual job performance, most notably in domains other than task performance. An important takeaway is that employee green behaviors can function as task performance, citizenship performance, or CWB depending on the occupation and industry. The content of the Green Five (summarized above) can permeate all job performance dimensions.

Determinants of Employee Green Behaviors

Like all work performance behaviors, employee green behaviors are directly determined by three individual characteristics: knowledge, skill, and motivational choices of where, at what level, and how long to direct one's effort. Other individual factors, such as values, attitudes, personality characteristics, as well as various organizational interventions, contribute to employee green behaviors either by influencing choices and directing effort or by providing employees with the knowledge and skill needed to perform the relevant behaviors.

The vast majority of research on environmental interventions and education has focused on how to raise awareness of environmental problems and increase individuals' knowledge about how to solve them. Knowledge, skill, and awareness are key enablers of employee green behaviors. Awareness of environmental problems and the consequences of individual behaviors are preconditions for pro-environmental action, and a lack thereof is a major barrier (Hansla et al., 2008). Such awareness can lead individuals to develop moral norms about the need for environmental protection, as well as feelings of guilt in events of norm violation (Bamberg and Möser, 2007). However, more important than simple awareness of problems is knowledge about their causes and the actions necessary to solve them (Hines et al., 1986/1987). "It is important to know that something needs to be done, but it is even more important to know what and how to do it" (Dilchert and Ones, 2012b: p. 195).

Awareness, knowledge, and skill are necessary but not sufficient conditions for employee green behaviors. While an employee cannot act sustainably if he/she does not know how; simply knowing how does not mean that the employee actually *chooses* to perform green behaviors. For this reason, a great deal of psychological research on pro-environmental behaviors has focused on individual characteristics that influence environmental motivation – individuals' choices about which environmental behaviors they actually engage in.

A large body of research has examined the impact of demographic characteristics on environmental behavior (see Klein et al., 2012). Stereotypes of the 'environmental consumer' are frequently portrayed and discussed in popular media outlets. Individuals who are concerned about the environment and who perform pro-environmental behaviors are characterized as being young, often female, highly educated, and affluent. Research has shown only modest support for these stereotypes (Hines et al., 1986/1987). Education and income are only weakly related to environmental behavior. Pro-environmental behaviors are not the province of the wealthy, and general education does not necessarily lead to increased knowledge, skill, or motivation to perform pro-environmental behaviors. Gender is also only weakly related to pro-environmental behavior performed in individuals' personal lives, though women tend to perform more employee green behaviors at work than men. Age shows more complex relationships with pro-environmental behavior. Wiernik et al. (2013), based on their meta-analysis of general population samples, reported that although most age–behavior relationships were negligible, small to moderate relationships were found for engaging with nature, avoiding harm, and conserving resources. Older individuals appear to be more likely to engage with nature and avoid environmental harm. Perhaps more interestingly, although prior to 1995, younger individuals tended to perform more conserving behaviors than older individuals, this trend appears to have reversed. Based on data from the last two decades, older individuals engage in more conserving behaviors. Relationships between age and green behaviors in work settings are similar; older employees are somewhat more likely to perform conserving, avoiding harm, and influencing others' green behaviors (Wiernik et al., 2011).

Beyond demographic characteristics, environmental attitudes and values are key drivers of pro-environmental behaviors. Environmentally relevant values (e.g., altruistic, egoistic, anthropocentric, traditional; Dunlap and Van Liere, 1978; Stern and Dietz, 1994), connectedness to nature (Mayer and Frantz, 2004), and environmental perspective taking (Schultz, 2000) are all linked with pro-environmental behavior. Individuals are more likely to perform pro-environmental behaviors when they feel that the environment is worth protecting and that those pro-environmental behaviors will have an important positive environmental impact (Bamberg and Möser, 2007). This link between positive attitudes and behavior is especially strong when the behaviors are difficult or challenging (Kaiser and Schultz, 2009). When a behavior demands a great deal of effort, only those individuals who experience perceived value will bother to perform it.

One form of attitude that is vitally important for employee green behaviors is *environmental commitment*. Environmental commitment is defined as "the extent to which an individual is dedicated to environmental sustainability and is willing to engage in pro-environmental behaviors" (Mesmer-Magnus et al., 2012: p. 159). Individuals who are committed to the environment incorporate sustainability into their personal identities and act in ways that support this identity. When organizations adopt the environment as a key stakeholder in their operations, employees' commitment to the *organization*, the extent to which employees are bonded to and linked with the organization, also serves to support the environment. By combining individual environmental commitment with employee commitment to environmentally responsible organizational goals, strong motivation to perform employee green behaviors can be formed.

Recently, researchers have also begun to examine the influence of broader psychological characteristics and personality traits on individuals' pro-environmental behaviors. Broad personality traits show strong relationships with environmentally relevant behaviors. Wiseman and Bogner (2003) report that individuals low on agreeableness and conscientiousness tend to exploit environmental resources more than others. Furthermore, lower impulsivity and lower emotional stability (i.e., higher neuroticism) relate to conserving behaviors and preservation. Agreeableness and conscientiousness have also been found to relate to self-reported electricity conservation (Milfont and Sibley, 2012). Finally, openness to experience, conscientiousness, and extraversion appear to contribute to pro-environmental behaviors among students, and openness correlates with general conservation and adopting green habits and behaviors (Markowitz et al., 2012). In work settings, recent empirical research has also found that openness, agreeableness, and conscientiousness predict employee green behaviors (Dilchert and Ones, 2012b). Individuals who are responsible, considerate of others, and who place value in beauty, ideas, and experiences tend to act in ways that support environmental well-being.

An important method for examining individuals' environmentally relevant choices is to consider the reasons individuals cite for engaging in environmentally beneficial or harmful behaviors; what psychological functions do such behaviors

serve? These psychological functions are captured by *environmental motives*. Klein (2014) conducted a series of studies examining the motives individuals gave for their employee green behaviors. These studies identified 18 distinct functional motives grouped into four categories. *Prosocial motives* include performing green behaviors in order to benefit the environment, to help other people, or out of a sense of social responsibility. *Enabling capabilities* involve conditions that increase the ease or capability of sustainable actions, including performing green behaviors simply because the individual knows how to, out of habit or personal preference, or because environmentally responsible options were available or convenient. *Extrinsic motives* involve performing employee green behaviors in order to obtain some other benefit not relevant to the environment, such as performing an environmentally beneficial or harmful behavior for its health or safety benefits or out of financial considerations. Finally, *image motives* involve performing green behaviors in order to foster one's own or the organization's reputation, in order to conform with organizational or cultural norms, or because such behaviors are required. Of the four categories of motives, the intrinsically oriented motives (prosocial motives and enabling capabilities) showed stronger relationships with employee green behaviors than did extrinsic or image motives.

Improving Employee Green Behaviors

Methods to improve employees' environmental performance can take two broad pathways – focusing on individuals or focusing on interventions.

Focusing on individuals involves recruiting or selecting candidates who are likely to perform employee green behaviors with higher frequency. Environmental sustainability can be incorporated into organizational recruitment efforts, in order to attract environmentally committed individuals. This requires developing materials emphasizing organizational environmental goals, training recruiters to address environmental questions and issues, and targeting sources likely to provide environmentally passionate job applicants. Incorporating environmental messages into recruitment efforts can also lead to higher rates of applicant attraction and job offer acceptance (Grolleau et al., 2012; Jones et al., 2014).

Organizational staffing efforts can also target environmental sustainability by selecting employees using psychological characteristics that predict employee green behaviors. Many of the individual characteristics described above could be used to select employees, including environmental values and environmental commitment. Broad personality traits, such as conscientiousness, agreeableness, and openness, are especially promising as selection criteria for improving environmental performance because these characteristics are also notably linked to other important job performance dimensions, including task performance, organizational citizenship behaviors, avoiding counterproductive behaviors, and creativity and innovation. It is frequently believed that promoting environmental sustainability must come at the cost of other individual and organizational goals, especially financial goals. This is not the case. The same personality characteristics that lead individuals to be environmentally responsible also lead them to be productive, helpful, rule-following, and innovative employees (Ones and Dilchert, 2012b).

In contrast to focusing on bringing environmentally responsible individuals into organizations, an intervention-focused approach to improving environmental performance seeks to increase existing employees' green behaviors by increasing their knowledge, skills, and motivation. Research on environmental interventions in organizations is in its infancy, but many studies on promoting pro-environmental behavior have been reported in the broader social psychological literature. These interventions have been reviewed by Osbaldiston and Schott (2012). Pro-environmental behavior interventions can be grouped into four categories based on the psychological methods used to promote behavior:

1. *Salience interventions* increase individuals' motivation for green behavior by drawing attention to sustainable options and making performing such behaviors easier. These interventions include increasing convenience (e.g., placing compost bins in cafeterias), providing prompts (e.g., posting signs reminding drivers not to idle their engines), offering appeals to individuals' sense of responsibility (e.g., "Only you can prevent forest fires"), or enforcing requirements for green behaviors.
2. *Informational interventions* increase individuals' knowledge and skills to perform green behaviors. They range in complexity from providing mere justifications (why individuals should perform pro-environmental behaviors), to provide instructions (what steps need to be followed), to providing more detailed information about the consequences of environmental behavior, and finally to providing comprehensive education about environmental systems and the impact humans have on them.
3. *Monitoring and feedback interventions* involve tracking individuals as they perform environmental behaviors and tailoring the intervention based on their particular needs and behaviors. These interventions can involve providing feedback on how individuals are performing and where they can improve, as well as providing penalties, rewards, or incentives designed to lead individuals to choose environmentally beneficial actions over harmful ones.
4. *Psycho-social interventions* involve leveraging social, psychological, and perceptual processes to influence environmental behavioral choices. These interventions can include asking individuals to make formal commitments and set environmental goals, placing social models of effective green behavior in individuals' work environments, or improving individuals' self-efficacy for performing green behaviors. One form of psycho-social intervention that appears to be particularly effective is asking individuals to evaluate whether their environmentally relevant behaviors match their espoused environmental attitudes and values. The cognitive dissonance generated when individuals realize that their behaviors do not support their attitudes can lead individuals to consider and adopt specific alternatives that will better match their stated environmental values.

Each of these classes of interventions can be effective for promoting pro-environmental behaviors to some degree.

Figure 1 Impact of interventions on pro-environmental behaviors.

Figure 1 summarizes the relative efficacy of various interventions based on meta-analytic evidence previously summarized in Ones and Dilchert (2013, Tables 7.3 and 7.4). The most effective single interventions across settings appear to be placing prompts encouraging pro-environmental behaviors in strategic locations, cognitive dissonance exercises, and providing information on social norms (e.g., "You are using more energy than 50% of your neighbors"). More effective, however, are interventions that combine several approaches in order to support pro-environmental behaviors using multiple psychological pathways.

Conclusions

Environmental sustainability is a pressing societal issue, and the importance of developing our economies within the limits of the natural environment will only continue to grow in the future. Individual actions, especially the actions of employees in organizations, play a vital role in achieving, or failing to achieve, environmental sustainability. Understanding the diversity of behaviors in this domain, the individual characteristics that enable and motivate these behaviors, and the interventions that can be used to support and promote them, is of paramount importance for organizations hoping to achieve lasting organizational viability.

Abstract

In social work as in many professions, the learning process does not end after initial training leading to qualification or licensing. Professional development (PD) is a career-long process within which, via diverse learning activities, professionals refine and augment their knowledge and skills and undertake personal professional supervision to enhance critically reflective practice. PD is held to be vital in practice remaining competent, ethical, and optimistic. These elements of professional practice while seemingly virtuous are not innocent of the political and organizational contexts in which they occur. This article critically reviews PD, reflective practice, supervision in social work, and the role of higher education and research.

Continuing Professional Development

It is generally held that all professions need to ensure their members remain well informed about new knowledge and policy and are able to demonstrate continuing capability in core practice requirements. Some form of professional development (PD) or continuing professional education (CPE) is considered a vital mechanism to ensure that the profession is able to respond to the challenges of rapid change. In social work, such change includes the influence of world and local events on social problems, the challenges of international mobility, and the needs of new and changing communities.

In many nations, increased emphasis on quality assurance legislation has provided impetus to develop mandates for ongoing professional education and development, for example, where registration and licensing bodies set requirements for supervision and PD linked to eligibility for renewal of an annual practicing certificate. These legislative features encourage employing organizations to pay closer attention to the ongoing development of their professional workforce. While social workers are registered or licensed as individuals, the pragmatic world of health and social services compliance criteria, dictated by purchase agreements with funders, will ensure that some provision will be made. These legislative mandates may provide support for resources for continuing development but also shift the impetus for PD and CPE away from the individual practitioner (and her or his personal professional accountability) toward a more managed approach within organizational settings. This shift renders PD and CPE part of managerial control; ongoing education becomes an outcome, not a process (Beddoe, 2009).

CPE is both an individual and a corporate investment, and economic policy has promulgated the imperative of lifelong learning and its broad social and economic benefits (Beddoe, 2009). Current requirements of the quality assurance and regulation add pressure on employers to provide resources to support for social workers' continuing professional development (CPD). Table 1 summarizes the many elements of time and focus across PD and CPE.

A functionalist account of PD and CPE, focusing on compliance, provides only a partial and inadequate explanation of the significance of career development to many social workers and their organizations. In particular, higher educational qualifications have symbolic value for social workers as they help to mark out status within the profession (Beddoe, 2013). Jarvis (1996) argues that one of the consequences of the greater demarcation of professional workers is the need for recognition of being up-to-date which "connotes evolving expertise in a world in which practitioner knowledge is quickly rendered out of date by the fast pace of research and scholarship" (Dirkx, 2006: p. 37). The possession of a higher qualification may 'add value' for what it symbolizes rather than what it entails. Similarly, as continuing education becomes more closely linked to workplaces, many higher degrees are now available for part-time enrollment and are linked back to

Table 1 Time and focus of professional development (PD) and continuing professional education (CPE)

	Elements
Time	PD follows the period of preservice education undertaken by professionals in which they achieve a first qualification with eligibility for entry to their profession
	PD extends professionals' learning in the workplace
	PD is ideally ongoing throughout professional careers
	PD enables professionals to update with new knowledge and new practices over the course of a career
	PD supports professionals' progress from beginning to mature practitioners
	CPE may be integral to career development and promotion
Focus	PD maintains and enhances practitioners' individual competence
	PD includes participation in professional (clinical) supervision
	PD may be structured or unstructured, formal, and informal
	PD is generally separated from the main activities of work
	PD is often located within the workplace
	PD often delivers codified knowledge through 'best practice' guides
	CPE is generally found in an external institution
	CPE encourages intellectual engagement with knowledge utilization and creation
	CPE in higher education fosters a spirit of critical inquiry

the work context through practical work-based components (Jarvis, 1996). The process of credentialing can influence individual practitioners as they consider their value in the market. In the current era, social work is not dissimilar to other professions – it is subject to the impact of globalization, shortages or gluts of particular kinds of professionals, international markets for education and professional skills, and increasing specialization within broad occupational categories (Jarvis, 1996).

Consideration of PD for social work cannot occur without recognition of the complex social, political, and organizational contexts in which the profession is practiced. We live in an era where social work has been challenged in terms of its methods and foundations of knowledge. Lorenz (2012: p. 496) argues that the current ideological context in which social work struggles to retain legitimacy:

> is characterized by two core criteria: efficiency of procedures (exemplified by the rise of managerial approaches to service delivery systems) and individualization in the form of privatizing social responsibility and activating individual members of society to secure their own livelihood and future.

It is within the managed professional environment that Lishman (2009) suggests that there are two contrasting contemporary models influencing PD in social work. The first is a competency model, which is frequently developed in a top–down approach and reflects political and organizational rather than professional imperatives and values. Competency models are frequently dominated by instrumental and codified procedural knowledge and thus deliver what is felt to be known 'best practice' to practitioners rather than the skills for independent and critical inquiry. In the second approach, Lishman suggests a learning-based reflective practice approach (Fook and Gardner, 2007; Redmond, 2004), which incorporates "evidence-based and research-minded practice" (Lishman, 2009: p. 374). The problem is that the drivers for reflective practice and evidence-based practice (EBP) are quite different. The drive toward a positivist approach to support for social work activity remains highly contested and is frequently held to be linked to the contemporary agenda of efficiency and steering the privatization of responsibility for welfare highlighted by Lorenz above. For social work, the call for EBP has shaped much of the debate around the ongoing intellectual and PD of social workers.

Within the neoliberal regime, which characterizes many Western nations, social work is called "to prove its willingness to play a part in the restructuring of social solidarity systems from an essentially collectivist perspective to an individualized approach" in order to "secure recognition as a useful management tool" (Lorenz, 2012: p. 497). Lorenz argues that if social work aims to retain a critical stance toward the restructuring of the welfare state "then it becomes unwise to meet this challenge with the epistemological instruments derived from the positivist tradition that, from the outset, excludes references to the political context" (p. 497).

CPD in social work is thus not innocent of ideological elements and can be a site of struggle between the aspirational claims of the profession (including education) and the more pragmatic preoccupations of policy makers and managers (Beddoe, 2009, 2011, 2013). The increasing regulation of social work often brings these tensions to the foreground and it has been argued that regulation can be a Trojan horse, leading to more governmental shaping of social work education and supplanting the critical analysis that underpins social work in higher education (van Heugten, 2011).

This article will explore several significant aspects of contemporary PD in social work, such as reflective practice, the purpose and benefits of supervision in social work, and the role of continuing education in fostering social work scholarship and practitioner contributions to research. This journey will commence with a brief exploration of reflective practice, which has been widely adapted by many service professions as an essential component in ensuring professional competence (Kilminster et al., 2010) and has become central to the practice of supervision.

Reflective Practice

Kilminster et al. (2010) note that although reflective practice was initially developed as a way to address problems in professional practice, it has been adapted by educators and professional bodies as a mainstream practice. They argue that this process has pulled reflective practice away from the margins and in doing so reduced its critical and transformative dimensions. The development of 'critical reflection' to be briefly explored below is an important countering response within continuing education and development for social work.

The seminal contributions of Donald Schön (1983) underpin reflective practice. Schön stated that the knowledge base of a profession has four important properties: "it is specialized, firmly bounded, scientific and standardized" (1983: p. 23). The focus is on problem-solving. However, in the often quoted "swampy lowlands" (p. 42) of messy human service practice, Schön notes that the nature of the problems, the 'who' and 'what' of problem definition, and decision-making are highly contentious (p. 41). Effective practice thus requires more than top–down 'expert' intervention. In his influential work 'The Reflective Practitioner' (1983), he reported on an exploration of how professional practitioners worked in action, noting that those with reflective ability shared some common attributes. They were able to see each individual service user and his or her circumstances as unique, were accessible and flexible, and able to respond to unexpected concerns or behaviors in the moment or 'in-action.' Highly skilled professionals were not dominated by reliance on codified knowledge and rubrics based in what he called 'technical rationality' – ways of knowing grounded in science and procedure (1983: p. 21). Domination of practice by expert knowledge and tools can alter the balance of art and science now commonly understood as necessary in the helping professions. More reflective practice is flexible and essentially collaborative based in sensitive and enabling relationships. This work and the contributions of more recent scholars of reflective practice underpin much of current practice wisdom in social work.

Fook and Gardner (2007) have made a major contribution to reflective practice in clearly linking reflective practice to the core aims of social work as a profession grounded in social

justice and human rights, via the development of critical reflection. Clearly differentiated from more neutral notions of reflection, with 'critical reflection,' Fook and Gardner (2007) see a reflective approach as affirming in practice other ways of knowing, such as the role of personal experience and its interpretation in supporting a holistic understanding. Fook and Gardner (2007: p. 25) note the complexity of experience that practitioners encounter in their day-to-day work and the significance of a holistic approach that focuses on "the whole experience and the many dimensions involved: cognitive elements, feeling elements, meanings and interpretations from different perspectives." Such an approach facilitates the discovery of the kinds of knowledge relevant to the unpredictability and anxieties of modern-day practice. Fook and Gardner's critical reflection approach (p. 27) is "a model for improving practice," which involves: "A bottom-up understanding of theory and practice; exposing problematic gaps between espoused and enacted theory," closing the gap and placing value on "intuition, artistry, and creativity," and adopting a "contextual, holistic, and experiential approach." Such an approach seeks to uncover and address unhelpful assumptions and in doing so contribute to critical practice knowledge.

As reflective practice has become central in professional activities focused on the development and maintenance of competent practice, supervision is often identified as a site where it is fostered and practiced.

Supervision

Supervision is a core component of PD for social workers. Supervision is generally held to provide a major forum for facilitating reflective practice and learning. It can be defined as an interactive dialogue between at least two people, one of whom is a supervisor. This dialogue

> shapes a process of review, reflection, critique and replenishment for professional practitioners. Supervision is a professional activity in which practitioners are engaged throughout the duration of their careers regardless of experience or qualification. It is accountable to professional standards and defined competencies and to organisational policy and procedures.
>
> Davys and Beddoe, 2010: p. 21

It is generally held that professional supervision has been a core social work practice since the development of social work during the latter part of the nineteenth century with an initial focus on the administrative aspects (Tsui, 1997). There is a broad agreement about the three main functions of supervision being education, administration, and support. Hughes and Pengelly (1997: p. 42) proposed a triangular model where the three functions of supervision are managing service delivery, facilitating practitioners' PD, and focusing on practitioners' work. This model demonstrates the tensions inherent within supervision in the turbulent social work environment, where conflicts may be experienced as these functions compete for time and attention. A significant feature of Hughes and Pengelly's model compared with earlier functional models is the rejection of support as a function of supervision, with the authors asserting rather that support is a core condition. It is the supervision relationship in which support and trust are nurtured that creates the environment for honest and critical exploration of practice challenges.

In the 1990s, concern was expressed that supervision had been reduced to an audit and compliance tool, in an increasingly performative culture in public services social work (Payne, 1994). It was not uncommon for supervision to virtually disappear from its roots in an educative, reflective practice. Supervision has been restored to a central place in social work practice in recent times as it is frequently identified in major reviews of social work as contributing to good practice outcomes and ensuring ongoing practitioner well-being and retention.

Supervision in the Organizational Context

The status of supervision encompasses elements of paradox in the present era. Recently, supervision has entered a new phase of prominence as three main factors have led to changes in the wider social work context : first, the neoliberal preoccupation with performance management and second, and interrelated, the impact of 'the risk society' and the associated public challenges to professional practice (Davys and Beddoe, 2010). Fear of service failure, concern for public safety, and a deep fear of public criticism on the part of both regulatory bodies and governments have encouraged supervision to be harnessed as a compliance measure. The third factor, the promotion of supervision as a mechanism for securing social workers' well-being and retention in the profession, reflects the other side of the surveillance coin, the specter of organizational anxiety about the safety of workers.

While there are many aspects of the retrieval of supervision from a purely managerial space, along with recent expansions of function as a well-being measure, supervision seems ostensibly a benign practice; however, it remains a contested space. Adamson (2011: p. 185) argues that supervision is "not 'politically innocent' and subject to wider influences." Adamson (2011: p. 186) argues for a broad distinction between 'micro' and 'macro' issues in supervision with the former focused on "intra- and interpersonal concerns, the ethics of relationships, and quality-control issues of best practice." The 'macro' focus of supervision practice is on workforce and organizational concerns.

Centrality of the contextual dynamics of supervision will always be vulnerable to policy swings and practice trends and thus subject to different, unreliable interpretations by practitioners and managers. The linking of supervision and managerial surveillance is not entirely put to rest.

Over recent decades, new public management practices have had considerable impact on health and social work services with high-profile disasters and tragedies ushering in a plethora of performance measures, audits, and quality assurance systems. An impact of the preoccupation on quality assurance has been an undue emphasis on the administrative functions of supervision and a consequential shift away from the in-depth review and reflective critique of practice. Jones (2004: p. 12) described it as a 'trade-off' between managerial and professional concerns. Within a risk-averse political environment in social work, the oversight of practice

decisions can create stress and anxiety. Supervisors may fear simple mistakes that threaten reputations, to the specter of serious harmful events for service users, patients, colleagues, or the public (Beddoe, 2010). In highly surveillant, risk-averse environments, anxiety can stifle innovation and diminish creative and collaborative practice.

Within the third factor identified above, organizational concern about the well-being of workers has provided a strong argument to support more creative, flexible, and less compliance-driven approaches to supervision. In the past 10 years, supervision has become subject to increased scrutiny to examine its effectiveness. Mor Barak et al. (2009: p. 25) conducted a *meta*-analysis of research on supervision and noted that various dimensions of supervision "may have protective, proactive, or preventive roles in ensuring a positive work environment that can contribute to worker effectiveness." These dimensions include supervisory task assistance, social and emotional support, and supervisory interpersonal interaction (Mor Barak et al., 2009: p. 26). In the United Kingdom, a recent review of the research on supervision by Carpenter et al. (2012) found evidence that supervision is associated with job satisfaction and protects against stress, and "practitioners should insist that good supervision be provided by their employers" (p. 16). This review confirmed support for supervision that goes beyond tasks and compliance.

Adamson (2011) argues that the best responses to complex practice situations are found in attention to reflective practice, structural analysis, critical thinking, and ethically sensitive behavior. Supervision can create a space to create a less certain space, where assumptions – moral, personal, professional, or political can be challenged and alternative explanations and possible solutions developed. Such deeper exploration in turn may promote more effective management of emotions by making space for positive reappraisal of complex situations and workers' emotional responses (Adamson, 2011).

Supervision and Reflective Practice

As supervision has been revitalized within the profession, it has become subject to greater scholarship and development. Accordingly, supervision is promoted again as a core reflective practice within the profession's mission, bringing personal, professional, organizational, and political elements into a reflective space. Supervision contributes to the strengthening of professional identity in social work, to 'convey the mission and vision' of social work (Tsui, 2005: p. 11) and can bring the examination of culture, gender and class politics, discrimination, and institutional racism to the foreground (Hair and O'Donoghue, 2009). Excellent supervisors do not merely tick boxes in compliance reporting but are thinkers who have the ability to hold and explore the anxieties of practice while retaining a critical edge in stimulating supervision. Supervision is best conceptualized as an intellectual activity. How then to achieve all these lofty aims in supervision? At the 'nuts-and-bolts' level, a process needs to be learned.

An example of a reflective learning model of supervision combines an experiential learning approach with a contractual process of exploration within the supervision process (Davys and Beddoe, 2010). This reflective learning model is a cyclic process within a set structure with tasks for the supervisor and supervisee. It consists of four main stages, which the supervisor and supervisee go through when working on an issue brought to supervision. The session itself is bounded by beginning and ending processes that enable safe learning, the valuing of the process, and the transfer of learning into subsequent practice. The four main stages encompass the experiential learning cycle and are named 'the event'; 'exploration, including impact and implications'; 'experimentation'; and finally 'evaluation' (Davys and Beddoe, 2010: pp. 93–105). **Table 2** summarizes the key tasks and processes of this model.

Thoughtful and reflective supervision, well resourced and honored with education and specific PD, has a significant continuing contribution to make within the profession. As a practice, supervision needs to be further researched and developed so it becomes more of a reality and less aspirational.

Higher Education

Social work education varies widely around the globe. In some countries, it has been offered almost exclusively at undergraduate level with 3- or 4-year specialist degree as the standard path to entry to the profession. However, in many nations over the past decade or so, there has been shift toward a much greater provision of social work education at postgraduate level, as has been common in the United States. It is argued that social work must be a research-led profession and thus postgraduate study is needed, achieved by the inclusion of an honors year of study, including application of research methods and a dissertation. The graduate school model is also growing in strength where graduates in social sciences and humanities enter a master's program that embeds theory, clinical practice, and research. The increased focus on research literacy is laudable, but the focus remains squarely on educating social workers to be consumers and translators of research rather than producers. This is not a healthy state for any profession; given that the creation of a body of knowledge for practice is an essential component of professional status. Higher degrees by research lead to a greater emphasis on knowledge production and scholarly dissemination.

It seems probable that PD for social work will increasingly focus on research, whether this encompasses 'in-service' training to update people with distilled research findings or requiring new graduates to enter postqualifying education reasonably early in their careers. This latter possibility will largely depend on governments' willingness to invest in social work. Major reviews of practice in England, for example, have recommended that higher education plays a major role in CPE for practitioners including the development of postgraduate programs in child protection studies, but Moriarty and Manthorpe (2013) note that changes in the regulatory body of social work may mean a shift away from the idea of a nationally regulated framework of higher qualifications. Instead, a new approach will encourage employers and universities to reach agreements about the content and delivery of CPD and CPE. In many countries in the current economic climate, access to higher education becomes more expensive and many practitioners are reliant on the willingness of employers to support their undertaking higher degrees. In this climate, signals support the continuation of fairly pragmatic

Table 2 The reflective learning model for supervision

Beginnings	The start of the session involves two key tasks. First, the creation of the space for supervision and ensure both parties are fully present and able to attend the work of supervision. Second, the agenda is set and items prioritized.
Stage 1: The event	In this stage, the experience or event is identified and the story surrounding it retold, which will help clarify the goal for the session. Once explicit and realistic goals are determined, the session can move on to the next stage of exploration. This process encourages the supervisee to be an active participant and take responsibility for the supervision outcome. During supervision, the supervisor will assist to retain purpose and direction toward reaching the goal.
Stage 2: Exploration	During this stage, the task to explore the issue brought to supervision. This is not a time for the supervisor to prove her/himself by providing the answers. Rather clarification of an issue is strengthened by ownership on the part of the supervisee. The role of the supervisor is to assist in the exploration of the issue from different perspectives, some of which have not previously been considered and will help the supervisee arrive at a new understanding or decision. In order to balance the emotional and personal elements of the supervisor issue with cognition, the model divides stage 2 into two substages: *Impact-reflection*: Here the event is explored in relation to its impact on the personal 'self' – feelings, actions, beliefs, values, and links to previous behaviors. It is here that a supervisee may come to identify the emotional impact of the work and there is opportunity to vent and explore emotion in a safe environment. *Implications – conceptualization*: Following an adult-learning framework, emotional expression needs to be balanced with exploration of the cognitive aspects of the role. This involves application of an intellectual framework that assists the supervisee to integrate theory, standards of practice, ethics, service policies, and protocols with their professional self. By doing so, new understandings and strategies may be discovered.
Stage 3: Experimentation	This is the stage to test out whether solutions arrived at during the exploration are viable, examine potential challenges, and develop a contingency plan. This stage is vital to the success of implementing the changes or strategies, which have been identified into practice.
Stage 4: Evaluation	This relates to evaluating whether the specific issue has been addressed and if the reflective learning process has achieved its purpose. The stage does not signify the end of the entire supervision session. The cycle may be repeated for additional supervision issues.
Conclusion	Finally, the supervision session will end with time for the session to be considered as a whole, both the content and the reflective learning process. It is an opportunity for giving and receiving feedback between the supervisor and the supervisee and to make arrangements for future sessions.

top–down-driven CPD, rather than transformative education that is driven by critical inquiry (Beddoe, 2009).

In the international arena, despite some discouraging trends, there has simultaneously been growing emphasis on EBP in social work, which may offer a positive pathway to greater social work scholarship. In many Western countries, this development can be linked to the 'modernization' agenda of governments demanding standardized interventions and greater professional accountability. The EBP movement has advanced a strong argument that social work practice be informed and developed from the results of empirical research. This trend is not without critique and again can focus on distillation and delivery of codified knowledge rather than fostering scholarly work by practitioners. We should not be seduced by uncritical claims that EBP will solve all the problems of social work and its service users. Criticism of EBP includes argument that it privileges quantitative research; is based on a flawed understanding of social science; silences service users; and fails to adequately account for the ambiguities and complexities of social work practice (Beddoe, 2011). Social workers, it is argued, can be much more context-sensitive and aligned to the moral mission of social work and thus report the unique feature of service users' worlds. Participatory action research and collaborative research undertaken by practitioners can also bring new knowledge to policy development and associated practice improvement.

Research and Scholarship in Social Work Practice

Bearing in mind the cautions raised above, perhaps one of the most positive features in the contemporary social work PD landscape is the discussion taking place about the importance of practitioner research. This is happening in many countries around the world, and Lunt et al. (2011) report that there are many attempts to promote practitioner research, which extends further than practitioner studies carried out by individuals but includes collaborations and projects supported by academic institutions and organizations. While there may be many diverse aims behind these developments, a common goal is to encourage social workers to move beyond passive relationships with research and take up active roles in generating and utilizing research in practice contexts (Lunt et al., 2011).

It is hard to quantify practitioner research as much may not find its way into traditional published outlets. Practitioner research is more likely to involve small, highly local studies of an informal nature. Social work practitioners are often motivated to study existing data that are collected routinely in service organizations with a view to better understand the needs and experiences of service users in order to improve the responsiveness and quality of services offered. Lunt et al. (2011: p. 188) note that practitioner projects are often time-limited with a variety of research designs and methodology with a focus on evaluation and that such characteristics are common, irrespective of whether the drive arises from 'tertiary study, agency imperative, or practitioners themselves.'

A survey of the literature identifies many challenges to social workers in participating in more active forms of research activity (Beddoe, 2011). Most commonly cited barriers are matters of time, confidence, knowledge, and skill; skepticism that social workers need to do more than just process

information; access to extant research and literature and the practical resources needed to conduct projects. It is frequently noted that practitioners struggle to set aside and maintain time for research, as metric systems of allocation and timeliness of casework demand their attention.

The most difficult barriers, however, are likely to be those that have their foundations in those arising from the relatively fragile position of social work in professional hierarchies and the concomitant weak knowledge claim (Beddoe, 2011, 2013). Lunt et al. noted that professional "self-image may act as a barrier to practitioner research with social workers viewing themselves as helpers rather than intellectuals" (2011: p. 188).

It is an ethical and moral imperative for social work to make a contribution to the development and utilization of knowledge. This requires the development of social work scholarship and research especially in relation to the many enduring problems of our age. Critical inquiry can enable social workers to make use of knowledge gained in everyday practice to advocate both for service improvements and the removal of the numerous obstacles to full economic and social participation for peoples and communities. Practitioner scholarship utilizes the well-honed social work skills of observation, analysis, intervention, and review already demonstrated by highly competent practitioners to provide a window on the experience of many communities.

Conclusion

What then is the likely future of social work professional development? In the current recessionary era, it seems likely that social worker involvement in higher degrees by research will grow rather slowly, but as a profession in the grip of the professional project, social workers will seek to raise their professional capital through achieving higher degrees and undertaking scholarship (Beddoe, 2013). Advances in information and communication technology continue to grow and social media is likely to play a much greater role in supporting CPD but research and investment in such development is in its infancy in many countries. Further research is needed to explore whether social workers will find social media helpful (Moriarty and Manthorpe, 2013). The current debates about access to peer-reviewed research are highly relevant to social work. Much social work research is locked away behind commercial publishers' 'pay walls' and practitioners are often unable to access journals without their employer's assistance. Open-access journals, blogs, Web-based curated content already demonstrate great potential linked through specialist groups in social media. A highly information-literate graduate workforce will undoubtedly lead the charge for continuing access to up-to-date resources and opportunities to participate in research and development.

Abstract

Professions are characterized by special functions, strategies, structures, forms of knowledge, and sociocultural styles. The history of the professions investigates the ways in which particular knowledge-based occupations are institutionalized and organized in different times and contexts. The professions include the occupations of doctor, lawyer, professor, and engineer, among others. Professionalization refers to programs, projects, and processes affecting the social and symbolic construction of professions. The comparative history of the professions shows that paths, cycles, and types of professionalization may vary. Teleological understandings of professionalization and static conceptions of the professions are thus relativized.

Introduction

Professions are characterized by special functions, strategies, structures, forms of knowledge, and sociocultural styles. Professionalization refers to programs, strategies, and processes affecting the social and symbolic construction of occupation and status. In modern historical scholarship, the professions include the occupations of doctor, lawyer, professor, and engineer, among others. The history of the professions investigates the ways in which functional groups and status groups are institutionalized and organized in different times or historical constellations and contexts; and how the pattern of a profession is diffused, emulated, and adapted in processes of modernization, nationalization, and globalization. It shows how and why professions, in the restricted sense of the term, differ from the status groups and occupations of entrepreneur, merchant, artist, clerk, skilled manual worker (crafts, *métiers*) and the so-called semi-professions. Professionalization involves the formation of an occupation, on the one hand, and interrelated developments regarding the social division of labor, structures of authority, and sociocultural inequality, on the other.

Historical research on professionalization concentrates on such issues as the distribution of knowledge, influence, wealth, and power at a particular point in time; the social definition of behavioral prerogatives; the regulation of central values and functions; and forms of social and cultural exclusion. It is concerned with the motives, interests, and strategies of actors who either promote or hinder processes of professionalization. Recent historical research on professionalization has tended to oscillate between individualizing historical perspectives and systematic social science perspectives. The former emphasizes the peculiarities of particular professions or the special features of the professions in a particular historical context. The latter concentrates on general features, similarities, and convergences in time and space. International comparative research shows that while the professions are often concerned with the same or similar functions, problems, and tasks, these may be interpreted in different ways and institutionalized in different forms. Similarly, depending on the characteristics of a particular profession and on the particular historical circumstances, the paths, cycles, and types of professionalization and deprofessionalization may vary. By taking these points into consideration, historians have relativized both teleological understandings of professionalization and static or functionalist conceptions of the professions.

Definitions of Profession and Professionalization

Abstract models and temporally undifferentiated concepts of the professions have a heuristic value in historical research. Historians of the professions usually begin with a historical explication of the concept and then ask how ideas and sociocultural patterns are articulated in a specific context with regard to the relevant dimensions in particular domains. The individual dimensions and processes are more or less closely linked in concrete historical cases. The result is that the professions and professionalism find expression in a graded series of variations.

The professions are characterized ideally by the following series of interrelated dimensions: Capabilities and skills are justified scientifically or systematically. Professional knowledge is described in such terms as 'exclusive,' 'more profound,' 'inaccessible to lay persons,' and 'not easily understandable.' It is acquired in special institutions such as universities, professional schools, and internships with professionals. It forms the basis of the superiority of the professional over lay persons and clients. Also included in this body of knowledge are rules and attitudes which govern its application in a way which promotes trust between the professions, their clients, and their social environment. These include formal procedures, rituals, titles, a professional habitus of studiousness, collegiality, and altruism, and a general orientation toward the common good. The professions claim for themselves a specific style of earning a living that is characterized by the principle of remuneration 'befitting ones rank' and through specific forms of contract and recompense. The professions demand for themselves higher prestige. They develop specific organizations for collective integration, self-administration, self-control, and for the representation of their interests, such as the 'chartered professions' in England, the disciplinary councils and professional chambers on the European continent, and, more generally, professional associations of various kinds. The professions strive for 'autonomy.' Viewed historically, this means, first, exiting from relations of patronage with traditional secular and

clerical elites and, second, the reduction of external control and dependence on the state, on the market, on the rich and powerful, on clients or beneficiaries, and on employers.

Professionalization is a social project, which articulates itself in discourses on science, performance, honor, public welfare, and society and in the ideology of professionalism. It is intended to secure for professionals a high or midrange status in the system of social and cultural inequality.

The historical literature distinguishes between professionalization that is externally controlled and professionalization that is controlled by the occupational groups themselves. Similarly, it distinguishes between heteronomous and autonomous professions. In the classical research on the 'free' or 'liberal' professions, especially in the Anglo-Saxon literature, professionalization is understood largely from the perspective of members of the occupational groups themselves. In recent research, however, the analytical concept of professionalization is being used increasingly for professionals who are occupied in state and private administrations and enterprises as well (Burrage and Torstendahl, 1990; Perkin, 1989; Siegrist, 1988). Previously, and especially on the European continent, scholarly interest in professions was often guided by concepts such as 'higher education,' 'meritocracy,' 'bureaucracy,' and 'civil servants.' Recent research about artists, authors, and creative workers in the modern cultural industry and information business, discusses whether they conceive of themselves as professionals, emulate professionalistic patterns, and rely on strategies of formal professionalization (McClelland, 2003; Müller-Jentsch, 2011).

The historical connection between occupational role and social status is articulated concretely in concepts such as the 'gentlemanly professions,' the 'learned professions,' or, more simply, the 'professions' in England and the United States; *professions libérales*, *bourgeoisie à talents*, *capacités* in France; *gelehrte Stände*, *höhere Berufe*, *bürgerliche Berufe*, *mittelständische Berufe*, *Akademiker*, and *Bildungsbürgertum* in the German-speaking lands of Europe; *professioni maggiori*, *professioni nobili*, and *borghesia unmanistica* in Italy; 'intellectuals' in Western Europe; and *intelligentsia* in Eastern Europe (Siegrist, 1988, 1996; Freidson, 1986; Conze and Kocka, 1985; Malatesta, 1995; Charle, 1996; McClelland et al., 1995). In the twentieth century, professionals express claims to membership in the middle classes through discourses on the 'loss of middle-classness' and the 'threat of proletarianization.' Under National Socialism and Fascism, the meaning of the 'free professions' was hollowed out, as professionals were redefined as militant 'thinking workers,' who took part in the 'struggle of the volk and the master race.' In the Communist world, the concept of the socialist intelligentsia implied the transcendence of class relations, the end of occupational privileges, and the subordination of professionals to the state and the party. Modern western concepts such as 'technocrat' and 'expert' define the role and position of professionals independently from social or economic class.

Conceptions and History of Professionalization and Professions

The history of the professions begins in the high and late Middle Ages and in the early modern era with the autonomous corporate colleges of the higher professions (lawyers, physicians, university professors) and the lower professions such as surgeons and notaries (Prest, 1986; Betri and Pastore, 1997). The various 'premodern' professions have specific orders of knowledge and a relatively stable social position and legal rank in the society of estates and among the urban elites and middle strata. They enjoy privileges with regard to education, access to the professions, the practice of the professions, and ethical monitoring. The specific type of nonmanual work and the way of earning a livelihood distinguishes the higher professions from handicrafts and commercial occupations. The institutional pattern and the mentalities of the old European corporate professional culture varied according to the degree of the abstraction of knowledge and social proximity to the nobility, the patriciate, and the urban bourgeoisie. As a rule, the right to practice a profession was limited to members of a specific sociolegal category and to a specific territory.

The traditional culture of the professions came under pressure already in the rise of the premodern territorial state. It began to dissolve in the eighteenth and early nineteenth centuries, when authoritarian and bureaucratic societies of Europe reformed professions and brought them under the control of the state. At the same time, in radical–liberal, democratic, and egalitarian societies such as France in the revolutionary era, the United States and Switzerland in the mid-nineteenth century, the professions were largely deregulated or were established as free trades (Ramsey, 1984; Siegrist, 1988, 1996). The general orientation of the different professions varied between (1) loyalty to and dependence on the state, (2) a progressive–liberal worldview, and (3) the desire to defend or revitalize traditional professional cultures and corporate mentalities. Different professions displayed many similarities with regard to the level of education, the orientation toward science and scholarship, and the social position of their members. Nevertheless the various occupational groups often competed with one another for cultural hegemony, social prestige, and political power in the modern states and nations.

Institutionalization of Professional Training

The specific way in which education and training are institutionalized plays a central role in processes of professionalization. The states of the European continent led the way in the creation of theoretically and scientifically based training programs and in the transfer of such programs to (reformed) universities and elite institutions of higher learning such as the French Grandes Écoles. On the other hand, it is also true that (complementary) training through practice survived and even retained a central importance (trainees in state agencies, mandatory internships with practitioners, or, for example, when the first professional years serve, in effect, as a sort of apprenticeship). In Anglo-Saxon countries, the transition from 'training on the job' or 'shop culture' to 'school culture' has intensified since the late nineteenth century (Lundgreen, 1990). A comparison of the length of time required for professional training in different countries reveals significant differences, even for the same occupation. Some of these differences may be attributed to variations in the contents of training programs, while others depend on factors such as tradition,

restrictive state policies affecting the labor market, or exclusive strategies of the professions, and social elites themselves.

The Institutionalization of Professions

Beginning in the eighteenth century, it is important to distinguish between the legal institutionalization of the professions by the state, on the one hand, and the formalization and regulation that is intended and implemented by the occupational groups themselves, on the other. With regard to the latter, one must also distinguish among (1) the continual development of a pre-modern profession, which, in principle, was never dissolved (such as the English Bar); (2) the restructuring of professions, which had been temporarily deinstitutionalized (as was the case with physicians and lawyers in the United States); and (3) the formation of new professions by members of functional and occupational groups that first arose in the nineteenth century (especially engineers but also a number of other 'new' professions). All of these involve long processes, which typically culminate in accreditation through the state or the legislation.

In much of Europe, the state or the government or legislation took the initiative to regulate and institutionalize the professions (Siegrist, 1996; Ramsey, 1984; McClelland et al., 1995). The state, as the guarantor of the legal order, the promoter of culture, and as an intervening force in society, needed professional services and provided the professions with knowledge, rights, and duties. In this way, the state distinguished the professions symbolically from the occupations and functional roles of business, commerce, and agriculture, which had been deregulated through the abolition of guilds and the liberalization of the trades. Henceforth, the 'professions' in the restricted sense included only those vocations that were occupied with central goods and values or with securing property, honor, health, public order, morality, and science. In this new configuration of the professions, the 'old' European conceptions of profession, guild, and vocation were combined with 'modern' concepts of progress, liberal order, freedom, science, rationality, national culture, and civilization.

In contrast to liberal and democratic societies, monarchical, bureaucratic, and statist societies tend to define professionals as civil servants and to establish a specific hierarchy of the professions: at the pinnacle of this hierarchy are professionals in the civil service, who are followed by state-appointed professionals, then by highly qualified members of the 'free professions' and finally by those professionals whose training and practice are not prescribed exactly. In liberal societies, the hierarchy is less pronounced, and the free professions stand at the pinnacle (Siegrist, 1996). Since the late nineteenth century, professionals have been increasingly employed in private enterprises, such as industrial firms, banks, insurance companies, and research laboratories. The occupational and status groups of professionals who are employees develop their self-understanding with reference to the social types of the civil servant, the free professional, and the entrepreneur.

The professional and social types of the nineteenth century may be characterized as follows:

1. Professionals who are 'civil servants' are to a great extent bound in the service of the king or the state. If necessary, the individual lawyer, physician, engineer, or professor must disregard professional criteria and follow the directives of his superior. Due, however, to the increasing recognition of professional competence and of the indefinite tenure of higher civil servants, specific ideas and forms of professional autonomy also come into play in the judiciary, in the administration, and in higher education. Professions, such as the engineers who were educated in the elite technical colleges in France and then entered into the civil service, developed a special esprit de corps (Schweitzer, 1999);
2. Members of 'state-appointed professions' are holders of public office. Professionals such as these enjoy a kind of protected market (numerus clausus), but they are also monitored closely. Political appointment strengthens the authority of the expert in society but limits his autonomy, impedes the formation of a self-defined collective consciousness of the profession, and makes the organization of professional associations more difficult. Examples include the Prussian, Bavarian, and Austrian lawyers well into the late nineteenth century, the French and Italian court lawyers (*avoués*, *procuratori*), the Prussian county physicians, and the community physicians of Italy. In the late nineteenth century, some of these state-appointed professions were able to emancipate themselves from state protection, which had come to be viewed as patronizing. Linking discourses on political freedom and the free market with discourses on professional autonomy, they expressed the desire to become 'truly free professions.' Since clients increasingly made similar demands, many states changed the corresponding laws and regulations in the last third of the nineteenth century;
3. The 'free professions' are characterized by more elaborate forms of training and examination and distinguished titles. Credentials are derived mostly from the state, but the free professional must be able to adapt to one or more segments of the market for professional services. Minimal standards for both professional and ethical behavior are often regulated by law, at least in principle. In practice, such regulations are enforced either by professional courts of honor (disciplinary bodies with the authority of public law or executive boards of associations with informal authority) or by ordinary courts and clients; and
4. In those areas where professional functions are exercised in the form of free trade, the constraints of the market and the increasing authority of science and scholarship encourage informal processes of professionalization. Professionals are themselves motivated to improve their own qualifications. A professional elite defines professional qualifications, founds an association, and attempts to marginalize or discredit so-called semiprofessional practitioners.

Cognitive and Emotional Orientations and Strategies

In the eighteenth and nineteenth centuries, the contents, forms, and meanings of professional knowledge changed. As was the case with other societal elites, professionals formulated new scientific discourses and new models for professional conduct. The physician achieved greater recognition as a scientifically and practically trained healer and health expert (Huerkamp, 1985; Léonard, 1981), while the lawyer came to be viewed as a legal

expert and 'priest of justice,' who was responsible for the realization of the rule of law and for securing the rights, the property, and the honor of the citizens (Siegrist, 1996). The engineer was the chief proponent of scientific and technical progress, and was long considered to be an expert for administration, supervision, and organization (Schweitzer, 1999). The university professor and the teacher in the gymnasium or *lycée* were the experts for education, esthetics, and morality. Finally, the Protestant minister was the educated theologian, whose legitimacy was no longer derived from faith and piety alone.

The degree of the systematization of knowledge increased over the course of the nineteenth century but the superiority of the professions and the efficiency of professional conduct remained controversial for an extended period of time. This is evident in the debates over the competence of university-trained 'physicians,' practical 'surgeons,' 'herbalists,' 'quacks,' nuns, midwives, and orderlies, and, more generally, over 'professional knowledge' compared with the knowledge of 'lay persons.' The professions had enduring difficulties in their efforts to prove their greater efficiency and to legitimize their autonomy with reference to science. Therefore, they attempted to support their claims to professional autonomy with supplementary appeals to values and attitudes that they shared with most of their middle class clients and employers. The leading concepts in these efforts were independence, responsibility, impartiality, altruism, public service, acting 'in good faith,' and 'delicacy' (in the sense of tact and discretion). These values and attitudes were often codified in laws, professional regulations, codes of ethics, and professional manuals. In many cases, such moral standards applied to the whole person of the professional, i.e., not only to his occupational activities but also to his behavior as a private person, as a member of the social elites or middle classes, and as a good citizen as well.

Compulsion and persuasion served to bridge the gap between professional culture and lay culture. Professionalization was embedded in the historical development of power relations, social hierarchies, and disciplinary processes, which emphasized the compulsive character of the social action of professionals. With the spread of medical, legal, technical, moralizing, and educational practices, professional culture as a combination of knowledge and power penetrated all aspects of modern life and thought (Goldstein, 1984, 1987). The professions are said to have used their knowledge in order to secure for the elites and themselves social and economic advantages. On the other hand, empirical, social, and cultural–historical studies, in which concrete interactions between experts and lay persons are investigated, often conclude that experts were hardly able to realize their cultural projects in a pure form. For quite some time, lay persons avoided contact with professionals by seeking advice with regard to health from pastors or priests and by seeking legal council from union secretaries.

The historical record shows that the professions that were close to the state or involved with legally regulated cases and procedures were, as a rule, more successful in compelling recognition of their competence. In contrast, clients who made a short visit to the doctor's office, to a lawyer, or to a priest were not exposed to experts to the same degree. On the whole, the free professions had to rely more heavily on persuasion. This explains why symbolic performances, clothing, decoration of work spaces, rituals, and rhetoric are such an essential part of professional culture.

Professions, Markets, and Economic Situation

The rise of the professions in the nineteenth and twentieth centuries was due largely to the increased and increasingly differentiated demand of private and public customers for goods and services. To a degree, professionals were able to stimulate this demand as well. They fulfilled a continually growing need for the explanation of the world, the formulation and attribution of meanings, for edification, and for entertainment. Through their influence, questions of law and property, and of health and death were viewed less fatalistically. Many new opportunities arose for them in the construction trade, commerce, industry, banking and insurance, research, higher education, and also in agriculture. The professions profited from a general increase in prosperity and in the cultural needs of the middle classes. In the twentieth century, there was a rising demand for medical, social, and cultural services on the part of lower social strata, which had previously been neglected. Due to developments in the fields of education and insurance in the welfare state, and because of a general rise in income levels, these strata developed into a new mass market for professional services. The changing profile of their clients led to a revision of the traditional attitudes and practices of the professions.

Professionalization is often conceived as a strategy for market closure, cartellization and monopolization. Indeed, professional projects aim at reducing competition and stabilizing or increasing the incomes of the members of an exclusive group. Yet, comparative historical research about the bundle of professional aims and strategies, show that the relative weight of economic interests and the forms in which they are expressed, vary quite a lot. The economic situation of the professions has at no time and in no place been homogeneous. The spectrum ranges from the modest conditions of the lower middle class (*petite bourgeoisie*) to those of the upper middle class (*haute bourgeoisie*). Income and wealth vary according to stages in career development. They depend upon individual abilities and performance, on regulations governing fees and honoraria, on conditions in various markets, and on general economic cycles. In the nineteenth and early twentieth centuries, it was not uncommon for professional incomes to be augmented by supplementary, nonprofessional activities, by dowries and inheritance, by earnings from real estate, or by income from stocks and bonds. This was typical of the bourgeois and petit bourgeois milieus to which the professionals belonged through birth, marriage, or social relations. In the twentieth century, the income of professionals was still significantly higher than that of workers and the national average. Due to increasing competition, increasing recruitment from families of humbler background, and to economic and political crises, professionals have often become convinced that their heyday is behind them and that they are threatened with decline (Jarausch, 1990). Under these circumstances, there is often an intensification of conflict within the professions between protectionists and those favoring a more aggressive market orientation.

Beginning in the late nineteenth century, as the model of the free professions continued to spread, all of the professions became increasingly dependent upon the market. In reaction to

this, there were many debates among professionals over the 'overcrowding' of the market and the closure of the various professions. In such constellations, forms of a defensive professionalism and protectionist strategies became more popular in the professional middle classes. There was a general trend toward lengthening training programs and making them more difficult, in order to stem the influx of young aspirants. The pattern of discrimination against female candidates was widespread. In principle, women had been admitted to higher education since *c.*1900, but they were effectively hindered in practicing the classical professions for quite some time (Jacobi, 1994). In Central and Eastern Europe, members of religious and ethnic 'minorities,' who had been emancipated in the nineteenth century, still experienced discrimination when they attempted to gain admission to the professions. Due to their supposed 'over-representation' in universities and academic occupations, Jews were often made responsible for the worsening of the working conditions and the standard of living among professionals (Jarausch, 1990; McClelland et al., 1995). It was not until the second half of the twentieth century that discrimination on the basis of religion, ethnicity, and gender gradually came to be forbidden.

Particularism vs Universalism

Depending on varying perspectives among both contemporaries and historians, the modern history of the professions may be understood in terms of the nationalization of culture and society or in terms of the universalization of knowledge and the rise of an European or even global professional culture. In the process of nation-building, members of the professions became part of the elites, which supported the development of national society, politics, science, and culture. The national system provided them with opportunities and assigned rights and duties to them. As functional and cultural elites of the nation, they had a common interest in maintaining the interconnection of power, status, knowledge, and earnings (Léonard, 1981; Siegrist, 1996; Pue and Sugarman, 2003; Pérez-Perdomo, 2006). In both the public arena and in more exclusive spheres, they represented themselves through professional and bourgeois values and symbols; these included historical accounts, myths, and *lieux de mémoire* as well as cultural artifacts such as busts, statues, and portraits of famous professionals in public buildings. Professionals have tended to view their own structures, practices, and status as being nationally specific, even in those cases, where, in objective terms, there is a dominant international pattern or a transnational epistemic community, which is subject only to slight regional variations and nuances.

Comparative historical research and the history of institutional and cultural transfer relativize national interpretations and lead to significant revisions of national views of history. Such approaches have shown how states and national professions imitate and vary foreign symbol systems and institutions, when they are convinced that this will lead to an improvement in their performance and in their status in national and international competition (Ramsey, 1984; Lundgreen, 1990; Siegrist, 1996; McClelland et al., 1995). In some cases, occupational patterns that were originally imposed by European empires were maintained after the end of imperial domination. French models for advocates and for engineers were imposed on other lands during the Napoleonic era; but subsequently they were adopted voluntarily, because they were found to be compelling. The Habsburg monarchy influenced the structure of the professions in Southeastern Europe. Prussian prototypes exerted a strong influence in the development of the civil service and the professions in Northern Central Europe. During the colonial period, the model of the English and French professions diffused worldwide, and they have retained their attraction in the postcolonial era as well (Pernau, 2008). The Soviet model of the socialist intelligentsia spread after 1945 to the lands of the Eastern Bloc. In Europe, American patterns have competed with national ones at least since the 1980s.

Since the late nineteenth century, the European or universal character of knowledge and professional culture has often been celebrated at international congresses, but national patterns survived into the twentieth century. In Europe, these have only begun to weaken in recent decades, in the wake of liberalization, the integration of the European market, and globalization (Evetts, 1998). This is a clear indication of the fundamental difference between the professions and other occupations, which were liberalized at an earlier date and more thoroughly.

Historiography and Emphases in Current Research

Traditional historiography tended to be focused on a single profession. It served primarily to affirm a tradition and to establish an identity, to further the understanding of ones own profession and even to celebrate it, to delimit the profession vis-à-vis other occupations and semi-professions, and to justify the status quo and lend support to demands made in the public arena (Burrage, 1990; Siegrist, 1996). The oldest genres in the historiography of the professions include works which defend traditions, privileges, and customs in the face of threatening political, social, and legal developments or alternatively, they are polemical works by outsiders and civil servants who want to reform the professions. Since the nineteenth century, there has been a proliferation of biographies and memoirs of exemplary professionals, of *festschriften* on the occasion of anniversaries, celebrations, and congresses, of memoranda and surveys with historical aspects, and of learned historical treatises in encyclopedias on the general development and various special aspects of the professions. More ambitious historical monographs on particular professions first appeared in the late nineteenth century. The authors were typically either academic or leading members of the profession in question with an interest in history. Until recently, academic historiography has only showed a moderate interest in the history of the professions. Prior to the 1960s, both amateur and academic historians were more interested in individual professions than in typical aspects of the various professions and rarely took the approaches and theses of the sociology of the professions into account.

Precursors of the systematic historical comparison (and sociology) of the professions include works which, beginning around 1800, compared local and regional occupational ordinances and occupational conditions with foreign equivalents.

This sort of comparison and historical reflection was often conducted in connection with the preparation of national laws pertaining to professions. Around 1900, representatives of the new discipline of sociology began to take abstract and systematic approaches to individual professions, to groups of professions, and to specific aspects of the processes of professionalization. In the efforts of sociologists to discover the 'essence' of the professions or to develop a 'general theory' of the professions, historical aspects and cultural peculiarities were neglected. In the 1960s, the sociology and history of class and social conflict and pioneering contributions to international comparison, reintroduced a historical perspective to the study of the professions (see the historical overviews on the sociology of professions by Freidson, 1986; Burrage, 1990). These works inspired the new research on the professions in social history, in which the development of the professions is historicized and recontextualized, without, however, sacrificing the goals of systematizing, conceiving of historical types, and contributing to the formulation of a general theory. Today, the history of the professions is an established and dynamic field of social history, cultural history, the history of the sciences, and the history of education. Historical approaches to gender have shown why professionalization has, until very recently, remained a male phenomenon and how professionalization and gender have entered into specific kinds of symbiotic relationships.

Abstract

The study of professionals in organizations is about the intersection of two areas of enquiry that have quite distinct histories: the study of professions and the study of organizations. There have been times when they have been related strongly and other times when they have gone their distinct ways. In fact, the study of professions in organizations has gone through three, overlapping, phases since the mid-twentieth century. The first, started in the 1950s and particularly strong in the 1960s, was that of a critical examination of the role of professionals in bureaucratic organizations. The second, begun in the 1970s and continuing, critically examined the orthodox view of professionals and gave a more power-based, labor market analysis of their position and how it affected organizational labor markets. The third, which has its origins in the 1960s and 1970s, blossomed since the 1980s, emphasizing the dynamic nature of professionals in organizations and acknowledged the variety of organizational locations. This article outlines these phases, dealing with the central concepts and findings, examining the questions that each one raises, and pointing the way to the next phase of research in this rich field.

Professionals and Bureaucracy–1950s Onwards

The origins of the initial discussion of the relationship between professionals and organizations lies in the sociology of the professions and the discussions of defining characteristics of a profession. There are a number of contributions, but one that is often seen as central is that of Greenwood (1957) who suggested that professions have: a basis in systematic theory; prolonged training and certification; recognized authority; community sanction and legitimation; professional culture and codes of ethics. In essence, he came up with a set of traits or components that, when present in their entirety, defined the complete profession. This trait approach was echoed in a variety of ways by Wilensky (1964) and Hickson and Thomas (1969). There were two thrusts to these discussions. The first was to establish the characteristics that make up a profession. The second was to determine empirically which occupations were 'truly' professional and which were 'partly' professional and which 'aspired' to the status of a profession.

Out of these discussions came a relatively agreed upon set of characteristics of a profession that had structural and value aspects. The structural aspects were such things as a full-time occupation, a training and certification system, a professional association, and an ethical code. But, more importantly for the study of professionals and organizations, was the extension of Greenwood's notion of a professional culture into a set of values which encompassed peer reference, vocation, public service, self-regulation, and autonomy. When this work in the sociology of the professions connected with the sociology of organizations it was in terms of the relationship between the values held by professionals and those promulgated by the modern, bureaucratic organization. This relationship was seen primarily as antagonistic (cf Hall, 1968).

Through the 1950s and 1960s the great influence on the sociological study of organizations was Weber (1949). Weber's principal contribution to this field was his characterization of organizations in terms of the authority relations within them (systems of imperative coordination) and the ways in which such systems had evolved historically. Each ideal type of authority, charismatic, traditional, and rational–legal, had its associated organizational form.

Weber saw the rational–legal authority system with its organizational form of bureaucracy as the dominant institution of modern society. The authority system is rational because means are designed expressly to achieve certain goals and it is legal because authority is exercised through an office with its associated rules and procedures. For Weber the bureaucratic organization was technically the most efficient form of organization possible.

In terms of Weber's evolutionary history of social systems, bureaucracies represent the final stage in depersonalization. Offices (jobs) are held by experts who are arranged in a hierarchy. Rules and procedures provide predictability and consistency. Information is recorded and stored. Personal and business affairs are separated. There is 'the methodical attainment of a definitely given and practical end by means of an increasingly precise calculation of means.' Starting in the economic sphere, bureaucracy is such a potent method of organizing that it becomes characteristic of all areas of society such as education, government, politics, religion, and so on. Much of organizational analysis of the 1950s, 1960s and 1970s was essentially concerned with establishing, extending, and critiquing Weber's notion of bureaucracy (e.g., Pugh et al., 1969)

As Abbott (1988) in his influential work has pointed out, this 1950s and 1960s view of professions had an underlying assumption of professionalization as a natural process; that is, a regular sequence by which an occupation moved to 'full' professionalism (Wilensky, 1964). Essentially, this view, together with 'the search for bureaucracy' produced a unitary view of both professional occupations and organizations. Professionals, it was suggested, were socialized into occupations where the key values were autonomy, peer control, and vocation. For example, Hall (1968) operationalized

professional values as the professional organization as a reference, a belief in service to the public, a belief in self-regulation, a sense of calling to the field, and feelings of autonomy. Bureaucracy was operationalized as hierarchy of authority, division of labor, rules, procedures, impersonality, and technical competence. However, his conclusion was 'an assumption of inherent conflict between the professional or the professional group and the employing organization appears to be unwarranted.'

Of course, both sides of this coin, the professional and the organization, could be, and were opened up to scrutiny. On the organizational side of the coin, Scott (1965) had put forward the notion of Autonomous and Heteronomous Professional Organizations. Pugh et al. (1969) distinguished between Full Bureaucracies, Workflow Bureaucracies, and Personnel Bureaucracies as well as Implicitly Structured organizations. The point of these taxonomies and typologies was to open up the possibility of there being organizational forms in which the values espoused by individual professionals would be embraced and protected, thus potentially transforming the nature of the debate beyond an inherent conflict.

On the other side of the coin, the changing nature of professions was being stressed together with their organizational locations. Two issues are important. First, there was a trend of increasing professionalism within bureaucratic organizations. Occupations were arising that claimed professional status, such as social workers, nurses, and managers. These were bureaucratically produced and located occupations. Second, Hastings and Hinings (1970) suggested, from their work on chartered accountants, that there were established professions that carried out tasks that were centrally located in bureaucratic organizations and that, as a result, there was little or no conflict between professional and bureaucratic values in these situations.

This 'opening up' of both organization and profession led to new developments in understanding professionals in organizations. However, this theme of potential conflict between certain forms of organization and professionalism continues today. For example Raelin (1991) has examined the management of professionals in organizational contexts, writing about 'the clash of cultures' when generic managers are responsible for professionals. In the UK, and Europe more generally, there has been a concern with 'The New Public Management' and its organizational impact on professionals employed in healthcare, government at all levels, and education. The concern or thrust is still that there are incompatibilities between professional ways of working and values and certain kinds of organizational principles and practices. It continues to be a fruitful area of study.

Professionals in the Labor Market–1970s Onward

The second phase, begun in the 1970s and again, continuing until today, critically examined the orthodox view of professionals and gave a more power-based, labor market analysis of their position and how it affected organizational labor markets. The basis for this was laid down in critiques of the 'professionals in organizations' approach in the previous decades. The previous research questions had been anchored firmly in issues about the structure and values of professionalism with notions of an underlying process of professionalization arising from the nature of work in modern economies (Cooper and Robson, 2006).

The problems that were raised continued the opening up of professional occupations away from a homogeneous view of them. The uneven nature of professionals was stressed; that is, they could not and should not be considered as a unitary set of occupations. Similarly, the rise of the bureaucratic, organizationally based professions both in the context of the state and the private sector was recognized more fully. Abbott (1988) calls this the 'monopoly school' which attributes developments in professionalization 'to a desire for dominance or authority' (p. 15). The occupational/professional project is to control the conditions of work (the labor process and the labor market) and to increase and maintain occupational status and power (Johnson, 1972; Larson, 1977; Friedson, 1986).

The issues raised by this approach 'dislocate' the relationship between professionals and organizations both because it makes our understanding of professional occupations more complex, and also because it shifts the locus of debate away from values and structure to power and control. Indeed, the connection of this critique of the functions of professions is not as strongly related to the theme of professionals in organizations as the theories being critiqued. The emphasis becomes recentered on the nature of a profession and the professional project. In particular, the claim to professional status by an occupational group, for example, social workers, is seen as a way to control entry to the occupation and the demand for membership, and to establish an authoritative position within the labor market.

In a sense, the connection to organizations is primarily through an analysis of the rise of new professions and a continuation of the theme of 'the professionalization of everyone' (Wilensky, 1964). Because a key question to be answered is why new occupations make the claim to be professional, that is, the professional project, the examination is, in part, one of organizationally based occupations. Thus, the issue of professionals in organizations is not one of 'traditional,' autonomous professionals coming to terms with the rise of the bureaucratic organization, but the establishment of functionally and bureaucratically derived new occupations as professional. The issue for the new professional in this organizational setting is to acquire authority and control the conditions of their occupation's existence.

Thus, the professional/organizational relationship is not one of adaptation between two different sets of structure and values, but of an occupational group that is functionally defined and organizationally embedded acquiring the legitimacy and dominance that comes from professional status. The professional/organizational relationship is one of power plays, control of the labor process and fights over legitimacy that are played out both in the organizational setting and the institutional/regulatory setting within a particular society. This approach continues to be part of the discussion of professions in organizations and is to be particularly found in discussions of the healthcare sector (Friedson, 1986; Larson, 1977) and of the new public management. One of the issues that is raised by this stream of theorizing is that of the 'semiprofessions.' This was an attempt to distinguish between fully professionalized

occupations and other occupations that aspired to professional status. These latter occupations tend to be primarily those that are organizationally produced and located and where the individual occupation members do not work as independent practitioners. Johnson (1972) sees this distinction (and the use of other descriptors such as 'quasi,' 'marginal,' or 'limited' professions) as an illustration of power relations between occupational groups. For him, professions retain positions of authority vis-à-vis the semiprofessions, whose claim to professional status is contested. As he puts it, 'the pervasiveness of the ideology (of professionalism) is not indicative of the extent of professionalism (p. 59).

The theoretical and research issue of competition between groups for professional status continues to be an important topic. Several writers have observed the phenomenon of stratification within the professions. Abbott (1988) observes that interprofessional competition is a fundamental fact of professional life with jurisdictional disputes between occupational groups over claims to particular expertise and knowledge bases. And with more and more occupational groups that lay claim to such expertise and knowledge being strongly based in organizations, then the dynamic between professionals and organizations changes, on both sides.

Professionals in Professional Organizations–the 1980s Onwards

The third phase, which has its origins in the 1960s and 1970s, and blossomed in the 1980s and 1990s, emphasized the dynamic nature of professionals in organizations and acknowledged the variety of both professional and organizational locations. The issues of the variety in professional settings had been increasingly raised and, at the level of the professional system, Abbott (1988) has pointed out that there is continuous competition and jurisdictional disputes between professional groups as they dispute claims to expertise. Similarly, on the organizational side, the typologies and taxonomies of organizations both differentiated between types of bureaucracy and introduced new organizational forms.

This discussion has emerged in two different forms. The first is setting the discussion within the changes occurring in national and international economies. As thinking about 'the new economy' and 'globalization' has developed (Aharoni and Nachum, 2000), so two issues have been emphasized which bring together much of the previous theorizing about professions. On the one hand there is the rise of new occupations which claim professional status. For example, in the software development industry there are computer engineers, software engineers, and systems analysts who are highly educated but operate in paraprofessional environments across boundaries of time and space. Financial services have grown rapidly, as has the whole sector of business services, and along with this have come investment analysts, financial planners, and mergers and acquisitions specialists whose professional status is unclear although one sees the same processes as were written about in the 1960s and 1970s, namely those of educational qualifications, professional associations, examinations, and designations and the ideological claim to professional status.

On the other hand there is the rise of the 'knowledge-based organization' (Alvesson, 1995) together with the development of concepts such as the flexible organization and the learning organization. The suggestion is that organizations of the new economy are increasingly different from the various kinds of bureaucracy of the old economy. One of the reasons for this is that they are more service-based and that those services require highly educated employees who, in value terms, are much more like the 'old' professions, being committed to autonomy, vocation, and collegiality. These new organizational forms are seen as much more friendly and hospitable to professionals. Also, it is suggested that these forms are spreading into old economy organizations as they respond to the rigors of global competition.

The second form of the discussion is a renewed interest in the professional service firm, for two different reasons, each connected to new organizations and new occupations. Peters (1992) and Alvesson (1995) have suggested that the professional service firm is an example of the flexible, knowledge-based organization; that there is a wealth of experience in these organizations from which the newly developing knowledge-based firms can learn. But, at the same time, with the explosion of knowledge-based services, and, in particular, the tremendous expansion of business services in OECD economies, there is much more competition over professional jurisdictions. If one takes the example of the 'Big 5' accounting firms (formerly the Big 8 and the Big 10), there has been a continuous expansion of services within these firms and more and more integration across services and across nations (Greenwood et al., 1998).

The same processes are at work within other professional jurisdictions and professional service firms. In law, for example, there are strong internationalization pressures. Also, there is much discussion over the multidisciplinary practice, allowing nonlawyers to have a controlling interest in law firms. In 2000, the Law Society of New South Wales (calling itself 'the most progressive legal jurisdiction in the world') voted to allow multidisciplinary practices in law firms and also to allow them to incorporate.

Part of the process of defining these issues and also a result of them being articulated has been a rise in interest in the professional service firm (PSF). There were classic studies by Smigel (1964) and Montagna (1968) that examined the ways in which professionals operated in the professional service firm. But because of the concerns of theorists with issues of the rise of the bureaucratic organizational form and the response of professionals to that, and the concern with the monopoly critique, there was little or no interest in studying the professional service firm *per se*, even though it was the implicit, professionally hospitable setting contrasted with the bureaucratic form. It is this which has become the focus of much interest and research in the past two decades and in its own way it reflects issues of professionalization and bureaucratization, although the latter has been recast as managerialism and located in the context of knowledge-based organizations and globalization.

The theoretical and empirical location of studies of professional organization has been, primarily, in either the professional association and system or nonprofessional organizations. Very little study had been done of professionals in

professional organizations, organizations that can be described as PSF. One important dimension in understanding professions in organizations is the extent to which they are primarily located in professionally dominated organizations or in other kinds of organizations, the so-called bureaucratic professions. For example, practicing lawyers are employed primarily in law firms that are organized as professional partnerships; only a small proportion are employed outside legal practices; for example, as corporate counsel or as lawyers within the public defender justice system. Accountants tend to be split about 50/50 between private practice and employment in private and public sector organizations. However, almost all accountants are trained in private practice. Engineers are employed overwhelmingly in private and public sector organizations with only a small proportion of the profession being employed in engineering consulting firms. And engineers receive their postuniversity professional certification training in a wide variety of settings.

There are three points to be taken from this. First, professionals work in a variety of organizational settings, something that has been ignored in much previous work. Second, there are some professionals who primarily work in bureaucratic settings and experience little or no conflict. Hastings and Hinings (1970) showed that chartered accountants working in industrial settings experienced little role conflict and they argued that part of the activity of accountants is to bureaucratize others. Similarly, the debate over the semi-professionals such as social workers, teachers, and nurses centered around the fact that they were located entirely in bureaucratic organizations and did not have independent, autonomous practices. But, third, the arena of professional work that had been ignored in particular was that of the professional service firm in spite of the fact that implicit in many analyses of professionals, their location in independent professional organizational settings was considered to be very important as the archetypal setting for an autonomous professional practitioner.

Much of the work of the 1980s and 1990s has been concerned with understanding the nature of the professionally based, private practice organization (Nelson, 1988; Brock et al., 1999). As this work developed it also embraced the theme of bureaucratization although in a different guise, as managerialism.

This initial work was concerned with elaborating the nature of the traditional professional service firm, which Greenwood et al. (1990) typified as the P^2 form. The P^2 stands for the two key elements of professionalism and partnership. The PSF is an organization whose core workers are professionals. Traditionally they are from one dominant profession such as accounting or law. And the governance system of the organization is a partnership where the senior members of the professional group jointly and severally take responsibility for the direction of the firm.

There are a number of organizational consequences to these twin defining features. In human resource terms, one is the 'up or out' system or tournament. Young professionals either make it to partner or leave the firm. Organizationally, they are relatively loose structures, representative and collective decision-making with management being something that is done after dealing with clients. Issues of management and methods of organizing are not issues that are seen as important to discuss in the P^2 firm. The emphasis is on the individual professional and their ability to do good professional work. There are clearly strong echoes in this of the kinds of discussions that have arisen in the 1980s and 1990s about the knowledge-based firm with its employment of highly qualified individuals who are applying new, and sometimes esoteric knowledge, and, it is suggested, require freedom and flexibility to achieve results. In the P^2 organization, interesting work and the freedom and flexibility to do it are prized.

However, the nature of the professional firm has been changing due to changes in the institutional and market contexts of professional work. Because of the development of the new economy and the rise of services generally and business services in particular, there have been increasing pressures on the established professions such as law, accounting, and medicine. For more than a decade now, Western economies have been in a period of deregulation with the ideology of the market being dominant. Thus, jurisdictional boundaries have blurred and the level of *inter*-professional competition has increased. The rapid rise in the numbers of management consultants, financial services advisors, software development engineers, information technology consultants, media and marketing occupations, etc. has changed the dynamics of professional organizations. Similarly, there have been substantial changes in markets. On the one hand the demand for these professional business services has increased markedly, making it one of the most rapidly growing sectors in many economies. But the demands for these services are from increasingly sophisticated clients, operating on a global scale.

It has been suggested that a major consequence of these pressures and changes is that the professional, P^2 organizational form is in decline (Brock et al., 1999), and that it is being replaced by forms that place a greater emphasis on managerialism (Cooper et al., 1996). Cooper et al., (1996) named this new organizational form in professional firms the Managed Professional Business (MPB). In such an organization professionalism becomes centered on developing lines of business, hierarchies develop, strategic planning is introduced, targets are more binding, and decision-making rests in the hands of management teams rather than the partnership at large. So, the argument goes, the terms and conditions of work in the MPB move towards those of the regular corporation. However, this can only go so far because of the knowledge-based work of professionals (Rose and Hinings, 1999).

What this suggests is convergence for professionals in organizations, but of a new kind. It is not convergence around either professionalism or managerialism (bureaucratization), *per se*, but around a combination of these which is organized around the increasing role of knowledge in 'postindustrial,' service-based organizations. As yet, we have not sufficiently tracked these kinds of developments to write authoritatively about them.

Conclusion

So what can we conclude about research in this rich field and the status of our current understanding? There are a number of things. A very important one is the continuing theme

of the potential conflict between professionalism and bureaucratization and/or managerialism. That is, the notion of a professional encompasses values and cultural statements that are inimical to the forms and cultures of hierarchically organized, profit-driven corporations. However, this continuing theme has been modified in two important ways, both of which require much more study.

The first is the opening up of the idea of the professional. There is still a tendency to work with ideas of 'true,' 'full,' or 'traditional' professions that are seen as archetypal or at least worked with as ideal types. But, much of the original work on the professional–bureaucratic relationship, and, in particular, the ideas of the monopoly school, suggested that there are a range of professions exhibiting varying degrees of compatibility with bureaucratic working. More research is needed which starts from the *diversity* between professionals, rather than the assumption of homogeneity. There are still incompatibilities between some professional ways of working and their associated values and some organizational principles and practices. But whether those professions that have evolved from bureaucratic organizations have more compatibility with those forms is still very much an open question, and it needs to be connected to issues of claims to professional status and competition between occupational groups for professional status.

The issue that Abbott (1988) sees as central, namely, interprofessional competition and jurisdictional disputes between occupational groups, should be related to the types of organizations within and between which such competition and disputes take place. The healthcare setting is a particularly good one for examining these kinds of issues because of the numbers of professional groups involved.

A second modification to the professional–bureaucratic opposition thesis lies in the variety of organizational settings and their changing nature. While the death of bureaucracy is much over-stated, there is no doubt that new organizational forms are emerging that emphasize knowledge acquisition, use, and dissemination, together with flexibility and autonomy in organizational working. We might argue that the organic, flexible design is the 'new' organizational form. But there is a range of established and emerging forms within which there are differing responses to expertise and professionalism (Van de Ven et al., 2013).

A further development of these themes comes from our increased understanding of the role and nature of the professional service firm. Within the 1990s more and more interest and research has been centered on, *inter alia*, accounting firms, law firms, management consulting firms, and engineering consulting firms. These are, of course, the archetypal sites for the study of professionals within settings which should be the most accommodating because they are organized around professional work and managed by the professionals themselves. But they are also operating in changing institutional and market environments and face intra- and interprofessional competition. More research needs to be done on the way in which these professional fields are being restructured, new occupational grouping emerging, new organizational forms developing, and the organizational–professional relationship being changed. Part of this is also that there are important differences *within* as well as *between* professionals in terms of organizational setting.

Finally, an important and intriguing topic to be examined is the possible convergence of professionals in organizations and organizations of professionals. That is, on the one hand, many 'nonprofessional' organizations are becoming more knowledge-based and are experimenting with more flexible and autonomy-based organizational forms (e.g., Duska, 2005). On the other hand, professional organizations are moving into new markets, facing more competition, changing their knowledge base, and growing in size. In doing this they are becoming more managed, more strategic, and possibly decreasing some aspects of autonomy and flexibility. What they can offer is challenging work with major clients. This suggests a new kind of convergence, combining professionalism and managerialism (bureaucratization), due to the increasing role of knowledge in 'postindustrial,' service-based new economies. These changes present a real challenge for research.

Abstract

The sociology of professions studies the organization of expert work. Until quite recently, such work has been characterized, above all in Anglophone countries, by a particular social form – the profession – uniting individual practice, collective association, specialized education and examination, and corporate discipline. Recent historical changes have brought the organization of experts into a more uniform pattern worldwide, as this older 'professional' form of organization has broken down under the pressure of salaried employment, rising state dominance, and an increased 'capitalization' of expert work. (At the same time, however, the English meaning of the word 'profession' seems to be becoming standard.) Studies of professions have reflected these developments. Early twentieth century work was typological, a style that gave way to functionalism in the 1950s. The 1970s brought a critical, 'professional power' school, which in turn gave way in the 1990s to a concern with professional work and with the impact of state and capital on the professions. An important strand of the literature has considered the professional intelligentsia as a 'new class.'

The sociology of professions is a branch of the sociology of work concerned with the analysis of expert occupations. It analyzes their patterns of organization, types of work, and social status. Because the sociology of professions first arose in the UK and the USA, it took its name and much of its early conceptual apparatus from the pattern of expert work characteristic of those countries. In recent years, however, the field has become more international, a change that is transforming both its empirical base and its theoretical superstructure.

Expert Occupations and the Sociology of Professions

The sociology of professions first arose to study the particular social form taken on by expert occupations in England and the USA in the course of the nineteenth century. This form was characterized by a combination of independent individual practice with some type of collective association. It usually involved specialized education, examination or licensure, service fees, and some form of autonomous discipline. By the early twentieth century, such a form was characteristic of medicine, law, accounting, architecture, and various other fields in the Anglophone world.

The first systematic analysis of these 'professions' was by Carr-Saunders and Wilson in 1933, who set forth a typological analysis of occupations resting on various 'traits' that were taken to characterize the professions. The Carr-Saunders and Wilson analysis had a hard time with the military and the clergy, which were certainly 'professions' in the English sense of the term. Moreover, it made no effective contact with the quite different organization of expert work on the continent.

The French, for example, have no word with the denotation of the Anglo-American 'profession.' The French do distinguish *professions libérales*, but these include only experts in free individual practice, not all experts of a certain type. *Profession* itself has much broader purview than the English 'profession,' as does the parallel *métier*. Moreover, the organization of French experts has historically been far more state-dependent than has that of Anglo-American ones. Nor was France the only problem. The word and concept of profession were no closer to the German culture of expertism than to the French. Indeed, the characteristic pattern for organizing expert workers on the continent has more often been through quasi-civil service arrangements than through autonomous 'professional' ones. The sociology of professions thus began as a study of a particular kind of expert occupation. Only gradually have historical and comparative study made the limiting character of that approach clear.

Historical Development of the Field

From the Carr-Saunders book of the 1930s up into the 1970s, typology remained the dominant strategy of the sociology of professions. Millerson (1964) presented a comprehensive summary of all the various qualities that had been used to define 'professionhood.' The typological approach eventually strangled inquiry, as investigators worried whether or not various groups really were professions. Indeed, a substantial literature grew up in this period on the 'semiprofessions,' usually felt to include teaching, librarianship, nursing, and social work. These fit the typological model in some ways (advanced education, licensing) but missed it in others (independent practice). The so-called semiprofessions were all largely female occupations, a fact that would later become more emphasized, but engineering, although largely male, shared many of the same characteristics. Within typological thinking, salaried employment of professionals presented a problem. A small literature in the 1950s and 1960s considered this problem under the heading of 'professionals in bureaucracies,' viewing such professionals as being under strong role strain because of the conflicting demands of profession and organization.

The typological model enabled the sociology of professions to come to a rapprochement with structural functionalism. In a celebrated essay, Parsons (1954) argued that professions were

rationalist (as opposed to traditional), that they exercised functionally specific authority (as opposed to undifferentiated authority), and that they were universalist (as opposed to particularist). The later Parsonian tradition saw the professions as squarely anchoring the pattern maintenance sectors of crucial social subsystems. The typologists' focus on the organization rather than the content of professional work accorded better with the early Parsons, however, which kept them apart from the later structural functional interest in the professions.

Throughout the early postwar period, students of Everett Hughes and others in the Chicago tradition continued to amass case studies of professions and semiprofessions. Many of these fit the typological model badly. Their dependent nature often mocked the high role structural functionalists assigned to professions. One way around this problem was to argue that professionalization was a characteristic process that many occupations had not yet fully traversed. In the 1960s and 1970s, sociologists of professions argued for a characteristic professionalizing process, a sequence of stages through which all expert occupations developed (Wilensky in 1964 provided the most famous analysis of such an argument).

In the later 1960s, the sociology of professions, like many other subfields, turned toward skeptical interpretations. Major reinterpretations came from Johnson (1967), Freidson (1970) and Larson (1977). This new 'professional power' interpretation saw the professions in a different light. Freidson brought a generation of detailed studies of medical workplaces and medical knowledge together with a theory of professional organization to argue that the structures of professional organization were hardly the direct outcomes of rational and functionally specific universalism. The power of doctors over nurses suddenly seemed less a matter of advanced training than an enforced local division of labor. At a much more general level, Johnson recast professionalism as one among a number of modes of occupational control. This argument was carried further by Larson's reinterpretation of professions as collective mobility projects in which expert groups sought rewards through control of certain markets for services.

The rise of the power school coincided with a wide new interest in professions among historians, particularly in the USA. Scattered works had previously considered some major professions – English law and US medicine, for example. But the 1970s and early 1980s brought a flood of works covering various professions in the USA, England, and to a lesser extent France and Germany. These various works covered periods from the early twentieth century as far back as the seventeenth and eighteenth centuries. Although there were (and remain) important lacunae, theorists of professions began to work with a new empirical base. Perhaps more important, the historians turned to the sociological literature for conceptual guidance and in many cases found little of use to them.

A number of other trends helped recast study of professions in the 1970s and 1980s. Most important was the steady drift of professionals away from independent practice and into corporate settings. On the one hand, this was simply a continuation of the trend toward larger and larger professional firms. In law, accounting, and architecture, sizable firms dated from the first half of the twentieth century, at least in the USA. Legal restrictions generally prevented this development both in the UK and on the continent. On the other hand was the development of multiprofessional firms, a pattern that had begun in architecture and now spread into areas like accounting, finance, and consulting. These largely professional firms were complemented by a much larger body of salaried professionals scattered throughout commercial and nonprofit organizations in the USA. By 1980, few US professions indeed were more than 50% made up of independent practitioners.

The rise of salaried professional work in the USA accomplished three things. First, it brought the US professional world much closer to the European pattern. The pattern of large-scale salaried employment by professionals had fascinated the French particularly, who had developed, in the concept of cadres, the notion of a technocratic intelligentsia as a new mode of occupational structure (see Boltanski, 1982). Second, the new salaried professional work reawakened the interest in the 'professionals in bureaucracies' problem of role conflict. Third, the new pattern led to new concepts of 'deprofessionalization' and 'proletarianization of professionals.' Although the latter term obviously derived from the attempt to develop a Marxist analysis of professions, both concepts attempted to come to terms with the notion – an absurdity under the 'professionalization' concept – that occupations could lose the perquisites and possibly even the form of professions once these had been gained. A wide variety of studies appeared in the 1970s and 1980s examining the degree to which professions and professionals were losing control of work and cultural authority as well as enduring more mundane changes in salaries and tenure.

By the mid-1980s, then, the sociology of professions looked quite different. It had lost nearly all touch with structural functionalism. There was confusion over which professions would develop in which directions at which times. A large new body of research opened to theorizing not only a wide variety of quasi-professional occupations in the USA and England, but also the expert occupations of the continent. In many cases, this new data had extraordinary historical depth (see, e.g., the comparative work in Cocks and Jarausch, 1990). In 1988, Abbott attempted to synthesize the entire area by refocusing the sociology of professions on actual professional work (both cultural and practical), turning away from the strong emphasis on the social structures of professionalism that had become the center of the literature. He envisioned a world of interprofessional competition over jurisdiction of work. Changes flowed into this world both from within professions and from beyond them, recasting some professions, privileging others, destroying yet others. Professions attempted to claim control of work in the workplace, before the public, and within the state, and the course of professions' histories was determined by the ensemble of this melee of interaction. Abbott explicitly attacked the still-continuing typological tradition for eliding large areas of work. For him a profession was anything that competed like one.

Although Larson and others had attempted some international comparisons, Abbott's heavy reliance on European cases, particularly French ones, presaged what became the major development in studies of professions in the 1990s. This was the trend toward examining the relation of professions and the state. Much of the most interesting work came from Europe, for example, Jarausch's (1990) comparative analysis of lawyers, teachers, and engineers in Germany in the first half

of the twentieth century. Krause (1994) has made the most general attempt at analyzing relations between the state and professions (and also capital), studying the USA, the UK, France, Germany, and Italy by means of case studies of law, medicine, engineering, and academics in each country. Krause's analysis focuses on the relative decline of professional autonomy and power in all these societies in the years after 1970. Both state and capital have increased their authority over professions.

The relation of state and professions has been underscored as an empirical question by the vast complications of creating standardized professional credentials in the European Union. The future of the sociology of professions will be greatly shaped by the theoretical developments necessary to analyze this process of internationalization of professional life. There is also a 'relations with capital' side to internationalization, encompassed in the largely unstudied complexities of the transnational corporations' use of professional services. There has been some study of 'offshoring' of professional services (e.g., of engineering services in telecommunications), but this particular capitalist attack on professional organization has not been studied in detail. In general, there is a startlingly small amount of work on expert occupations in the third world, with the possible exceptions of lawyers and, of course, the military.

Current Problems

The central present issue for the sociology of professions, then, is the question of how the professions will be reshaped by the economic reorganization that arose out of the crisis of the 1970s. Many of the recent transformations have long antecedents, particularly the drift to salaried employment with its questioning of professions' cultural authority. Other trends, however, are new or newly important because of the economic conjuncture. Internationalization has been crucial. By the late 1980s the restrictions on professional firm size began to fall in Europe, largely under the onslaught of US firms, particularly law firms and multiprofessional consulting firms, which were the only firms able to manage some of the huge legal and financial projects characteristic of the new international economy. The new gigantism has transformed relations both within the professions, and, more important, between the professions and the state. It is in the international context, too, that the question of the profession–state relation is most clearly posed.

But there have been important internal effects to rethink as well. The decline of medical power from the pinnacle portrayed by Freidson has given new meaning to the phrase 'proletarianization of professionals.' This decline, driven by reorganizations of insurers and regulators, requires revising general theory about how expertise is organized in society. In that sense, the sociology of professions is again confronted with a functionalist question: how is expertise to be produced, controlled and reproduced in modern societies?

The issue of state and capitalist control is only one side of this question. On the other is the issue of commodification of professional knowledge. It is at present much too early to know the effects of computer-aided design systems, medical diagnosis systems, and other expert systems on the future of professions. But it is clear that new theory is required. It is also clear that commodification will be used to further reduce the status of professionals (see Abbott, 1991).

Indeed, the field faces again the boundary question that has so long obsessed it. Earlier in this century, the boundary issue was 'what is a profession?' Given the new structure of employment relations, even in such highly professionalized surroundings as technological research firms and law firms, it is not clear what kinds of workers ought to be the subject of the sociology of professions. If the pattern of associational professionalism that gave rise to the field itself is either dead or transformed, then the field must retheorize its objects of scrutiny. Abbott's test – a profession is an occupation that competes by retheorizing others' work – presupposes fixed and organized occupations of a kind that simply may not exist under modern conditions of employment.

While the main focus of the professions literature has been on organizational and structural levels, some have insisted on a focus at the individual level, on the professionals themselves. The most general theme in this area has been a recurrent attempt to resolve the problem professionals (or expert workers) represent to Marxist theories of work. Originating in Djilas's book, *The New Class* (1957), the theme was continued in Bell's *Coming of Post-Industrial Society* (1973), with its predictions of a knowledge world of the future. Attempting to synthesize this literature Brint (1994) recognizes the intense pressures brought on older structures of professionalism by modern economies. He sees a decline of 'social trustee professionalism' as professionals become mere private citizens with particular interests. Perkin's (1989) much broader analysis argues that the idea of profession became a model for modern societies generally in the middle 50 years of this century. The ideal of an individual with personal 'knowledge capital,' combined with the notion of just reward, was in Perkin's view fundamental to the conception of the modern welfare state. In that state's fall, argued Perkins, fell the professional ideal as well.

Perkins' argument provides a useful conclusion. In his article on 'professions' in the prior edition of this encyclopedia, Talcott Parsons (1968) closed with the confident assertion that "the professional complex has already not only come into prominence but has even begun to dominate the contemporary scene in such a way as to render obsolescent the primacy of old issues of political authoritarianism and capitalistic exploitation." Now that history has shown him wrong, the sociology of professions must develop a theory that can stand the test of major historical change.

Profits

Abstract

This article outlines the main currents in the economic theory of profits from the eighteenth to the twentieth century – with particular reference to classical economics, marginalist or 'neoclassical' economics, the significance of profits for entrepreneurship, and Keynesian economics. It also examines how theories have connected the determination of rates of profit on capital, shares of profits in revenue, and absolute levels of profits.

Introduction

From the standpoint of the history of economic theory, the development of attempts at systematic explanation of the determination of profits has its beginnings in the mid-eighteenth century, most notably, with Richard Cantillon (1680?–1734) and François Quesnay (1694–1774) – the latter, the key figure of the French Physiocratic school. The object of their analyses is a more or less decentralized market economy, but not yet a social economy that could be regarded as genuinely capitalist. These are early contributors to what later comes to be called 'classical economics,' from William Petty (1623–87) to Karl Marx (1818–83), discussed in the next section. From the late-nineteenth century, there is the rise of the 'marginalist' school, commonly called neoclassical economics, which becomes dominant in academic economics after World War II, discussed in the following section. The significance of profits for theories of entrepreneurship is then examined. The penultimate section considers how theories have connected the determination of rates of profit on capital, shares of profits in gross revenue or value added, and absolute levels of profits.

But what of earlier Western thought? Is there anything that could be called 'theory' of profits to be found there? The systems of premodern Western thought concerning society, polity, and economy are first and foremost normative systems rather than descriptive systems. The most salient of these is medieval Catholic Scholasticism, a synthesis of the Judeo-Christian religious tradition and the ancient Greek philosophical tradition (as well as Roman law), most famously personified in the thought of Thomas Aquinas (*c*.1225–74). Perhaps the most striking theme of Scholastic thought that contingently touches upon profits is its strictures against money-lending for a return in the form of interest payments ('usury'). But there is no essential connection between these doctrines about interest and the subject of profits, since the former could apply to a world of only consumption loans (as distinct from loans for business purposes).

In any case, our purpose here is to elucidate descriptive doctrines; explanations of the existence of the phenomenon of profits, rather than ethical doctrines concerning the moral legitimacy or otherwise of profits. Nevertheless, in the course of the development of primarily ethical doctrines, elements of what may reasonably be called descriptive economic theory do arise in premodern thought. For example, Scholastic concepts of 'the just price' of a commodity gave rise to explanations of actual market prices, albeit crude; but little about the determination of profits that might be associated with those market prices. The concept of profits that arises in the eighteenth century belongs to a world of capitalism in which the systematic protection of individuals' property rights and enforcement of private contracts, together with free competition (in particular, the free mobility of capital and labor between different economic activities), establishes profits *as a systematic phenomenon with structure and a certain logic*, within a form of generalized liberal market economy. These institutions and forms of market organization only exist in fragmentary form in premodern times.

Classical Economics

The theorizing of profits in classical economics is focused upon rates of profits on capital 'advanced' or invested in production; that is to say, the ratio between the absolute level of profits and the value of capital invested, per time period. From the standpoint of profit maximization, this ratio is the magnitude that the owners or investors of capital are ultimately interested in: the proportion between their investment and their return. Anne Robert Jacques Turgot (1727–81) and Adam Smith (1723–90) are the earliest writers to clearly conceptualize profit rates so understood; but we concentrate on Smith, David Ricardo (1772–1823), and Marx in this section. The previous writers mentioned above, Cantillon and Quesnay, gave profits a systematic role in their economic theories, but not conceptualized in terms of the ratio of profits to capital invested. In Cantillon, profits appear as primarily a return for risk-bearing by 'entrepreneurs.' In Quesnay, they are the source from which capital accumulation by entrepreneurial farmers is financed, driving economic growth; but their persistence over time is difficult to rationalize in his theoretical framework.

Turgot and Smith, as well as the subsequent contributors to the classical tradition, decompose profit rates into risk premia that differ across different capital investments and a kind of 'pure' rate of return on capital investment as such (our term). See, for example, Smith (1976[1776]): book I, chapter 10. Hence, on the presumption of risk averse behavior by capital owners or capitalists (at least on average), there will be a kind of equilibrium structure of profit rates, even under competitive conditions, reflecting higher returns for riskier investments, although Smith has some doubts as to the predominance of

risk averse behavior. (Restrictions on competition – notably, restrictions on the free mobility of capital between different activities – will also cause profit rate differentials, with higher than competitive profit rates earned in activities less exposed to competition.) Smith is also careful to establish that, conceptually, remunerations for the functions of supervision and management of production, even if commonly referred to as profits, are, in functional terms, really a species of wages (Smith, 1976[1776]: pp. 128–130). This can be obscured when one and the same person is both the provider of capital to an enterprise and the manager of the enterprise. Smith and Turgot are also clear that if an enterprise employs borrowed funds to finance capital expenditures, some proportion of the profits will be distributed to the lenders as interest payments (e.g., Smith, 1976[1776]: pp. 112–113; Turgot, 1977[1769–70]: pp. 76–77, 85–88).

At the most abstract level of theorizing, it is common for the classical economists, as well as later economic theory, to focus upon a uniform or 'general' rate of profit in the economy, thereby leaving aside (to be treated separately) differential risk and the associated profit rate differentials under competitive conditions. As to what determines this underlying, uniform or general rate of profit on capital as such, Smith treats profits as an element of the realization, at the level of revenues or incomes, of the economy-wide production of a social surplus. This classical concept of surplus refers to that part of the gross product of the economic system which is available for free disposal, after replacement of the necessary inputs used up in the production of that gross output, including among those inputs the customary subsistence consumption of the labor employed. The question then is how the surplus is distributed or realized in the form of incomes. For Smith, the surplus is realized in the income forms of land rents, pure profits, and a part of wages, depending on the balance of bargaining power around the labor contract. But his theory of the actual magnitude of the general rate of profit rests on a highly unsatisfactory notion of 'competition of capitals.' Smith supposes that the greater the extent of capital accumulation, the greater the degree of competition between enterprises, and hence downward pressure on the general rate of profit (Smith, 1976[1776]: book I, chapter 9).

This does not amount to a convincing, determinate theory of the profit rate; and indeed, a generation or so after Smith, Ricardo demonstrates – albeit under rather restrictive conditions – that given the production methods in use in an economy, the general rate of profit is determined by, and inversely related to, the level of real wages (Ricardo, 1951 [1821]: chapter 6). The restrictive conditions Ricardo utilizes to arrive at this fundamental result involve, in particular, a labor theory of exchange value: It is supposed that the relative prices of commodities are explained by the quantities of labor time directly and indirectly required in the production of those commodities. Subsequently, it has been rigorously demonstrated that the inverse relationship holds under quite general conditions (e.g., Kurz and Salvadori, 1995). From the analytical point of departure of this inverse relationship, Ricardo's focus is the course of the profit rate over time, resulting from change in production methods over time. On the one hand, declining output from capital investment on poorer quality land as population expands will place downward pressure on the profit rate, given the real wages of labor. On the other hand, technical innovation associated with human invention can enable a rising profit rate, given the level of real wages. If the former factor dominates the latter, the general rate can fall to such a low level as to extinguish the motive to capital accumulation, bringing about a stationary state (zero economic growth; Ricardo, 1951[1821]: chapter 21).

In Marx's economics, considerably derivative from Ricardo's, profits are explained by 'exploitation' of labor, in the descriptive sense that profits are attributed to labor time worked by the average worker being greater than the labor time directly and indirectly required for the production of the worker's own consumption. The level of the rate of profit is then determined by reference to the proportion between the surplus labor time worked by the workforce (over and above the labor time required to produce its own consumption) and the labor time embodied in the capital invested in production (Marx, 1967: vol. 1 (1867)). (Thus expressing the profit rate, in terms of surplus labor time, does not seem to add any insight additional to the simple observation that in a capitalist economy the workers as a whole, as workers, do not receive the entire net product of the economy.) In the so-called 'transformation problem,' Marx seeks to translate economic variables (such as the profit rate), which he first expresses in terms of labor time, into the monetary values associated with competitive prices ('prices of production'). Marx also famously supposed a tendency for the general rate of profit to decline in the course of capitalist economic development, connected with the likelihood of crises under capitalism. But even within Marx's own theoretical framework, this is a contingent result. To translate it into more familiar modern language, in effect, Marx is expressing the general rate of profit as a ratio between profits per employed worker and capital per employed worker. The basis for a tendency toward a declining rate of profit is then the supposition of a rising capital-to-labor ratio, relative to any rising profits per worker. The possibility that any such trend toward a rising capital-labor ratio could be offset, or more than offset, by rising profits per worker is evident (Marx, 1967: vol. 1 (1867): pp. 304–305. vol. 3 (1894): pp. 232–240, 250–259).

Marginalist Economics

The key founding figures of this new approach to economic theory are William Stanley Jevons (1835–82), Alfred Marshall (1842–1924), Carl Menger (1840–1921), and Léon Walras (1834–1910). Rather than attempting to outline the particulars of the various efforts toward a theory of profits in these writers, and in those who followed their lead in subsequent decades of the twentieth century, we here seek to distil the essence of the theory of profits that arises out of this framework.

The fundamental point of departure is a conception of human psychology in terms of behavior governed by a pleasure/pain calculus. From this vantage point, economic behavior is explained in terms of the individual's maximizing net benefit ('utility' net of 'disutility'). Hence, for example, the desire to work and consume can be theorized along these lines. Suppose a person whose only marketable resource is his labor and who wishes to consume. He can supply labor, with a view to acquiring revenue, in order to enable consumption. On the

supposition that work generates disutility and consumption generates utility, the individual will have a desired labor supply and associated desired consumption demand that maximizes net utility – at least on the further supposition that there is increasing 'marginal disutility' from work and decreasing 'marginal utility' from consumption. Assuming there is sufficient labor demand and sufficient supply of consumption goods to satisfy the individual's desired labor supply and consumption demand, more time worked increases income, enabling higher utility from consumption; but notionally, as time worked and consumption increase, the increment of 'pain' from additional labor is rising and the increment of 'pleasure' from additional consumption is falling, so that at some point there is an 'optimal' combination of labor supply and consumption demand for the individual, where the rising marginal disutility from labor is just offset by the diminishing marginal utility from the consumption enabled by labor income.

The underlying characterization of human psychology here is certainly open to question (although 'utility' need not be supposed as cardinally measurable, but rather, merely as 'ordinal,' expressing individuals' preference rankings). But even if, for the sake of argument, one accepts the validity of that psychology, how can it apply to explaining profits from capital investment? With respect to capital, what possible analogue could there be to the supposed disutility of labor? Capital goods are produced means of further production; they are reducible to the labor, natural resources, and capital goods used to produce them; and those latter capital goods are in turn reducible to labor, natural resources, and yet other capital goods; and so on. So that, in the limit, capital is reducible to a 'dated' series of labor and natural resource inputs. What then is the painful contribution to production for which capital provision must be compensated by way of profits? The fundamental marginalist answer is the pain of *waiting*.

The provision of capital is understood to result from saving: abstinence from current consumption, or deferral of consumption into the future. It is the disutility of not consuming, or of saving, which must be balanced against the utility of future consumption resulting from current capital investment. Greater saving enables more capital investment and hence, higher consumption goods output in the future; but notionally, as saving and investment increase the increment of disutility from additional saving is rising and the increment of utility from additional capital (the 'marginal product' of capital) is falling. That is to say, supposedly analogous to the rising marginal disutility of labor and diminishing marginal utility of consumption (discussed above), there is rising marginal disutility of saving and diminishing marginal productivity of capital as the capital intensity (or 'roundaboutness') of production increases. At the level of the social economy as a whole, the general rate of profit (renamed 'the rate of interest' in the marginalist framework) is supposed to be determined so as to balance or equilibrate the aggregate supply of capital (saving) and the aggregate demand for capital (or investment, in flow terms). The equilibrium rate of interest induces the required saving. In this marginalist theoretical framework, there is no classical surplus – in the sense of a net product available for free disposal – to be found. Under competitive conditions, *all* remunerations to all 'factors of production' (notably, labor and capital) are 'necessary,' at least at the margin, in the sense that they are functional to ensuring the equilibration of the system.

This theory of the general rate of interest (profit) is embedded in the marginalist framework within a larger system of simultaneous determination of commodity prices, distributive variables (prices of factors of production), and economic activity levels. The economics of Knut Wicksell (1851–1926), who adopts the 'Austrian' approach to capital theory of Eugen von Böhm-Bawerk (1851–1914), provides the best illustration of the logic of profits within this larger theoretical system, from among what may be called the second generation of marginalist economists (e.g., Wicksell, 1934[1901], 1935[1906]). It is one thing to propose a kind of 'parable' in which an individual balances the disutility of work against the utility of consumption, or the disutility of saving (of abstinence from current consumption) against the utility of future consumption. It is another to demonstrate that this vision can be applied to explain outcomes in a mass social economy in which the plans of a myriad of maximizing individuals have to be coordinated so that the aggregated planned demands and supplies for each and every commodity and factor of production (notably, labor and capital) are brought into balance (a 'general equilibrium'). In particular, with regard to our focus here, this requires demonstrating how the rate of interest (along with all the other interacting variables of the complete theory) can coordinate the planned saving and planned demand for capital (or planned investment, in flow terms) of a myriad of individuals, with the saving and investment in general undertaken by different people.

The plausibility of this notion of the rate of interest (profit) as determined by the balancing or equilibration of the supply of and demand for capital (or of planned saving and investment) crucially rests upon the idea of demand functions for factors of production (in particular, capital), in which demand is a negative function of the relative factor price (for capital, the rate of interest relative to other factor prices). This construct has been subject to a decisive critique since the 1950s, although with alarmingly little impact on marginalist orthodoxy (Garegnani, 1990; Kurz and Salvadori, 1995: pp. 427–467). That critique turns upon a certain circularity of reasoning resulting from the heterogeneity of capital goods, which entails that the rate of interest (profit) is already presupposed in the prices of the capital goods that make up any measure of the quantity of aggregate capital demanded. It is to be noticed also that the hoped for marginalist 'general equilibrium' under competitive conditions entails full employment of the factors of production (a balance of demand and supply for factors of production as well as commodities). John Maynard Keynes (1883–1946) attacked this aspect of the marginalist theory in particular. In Keynes's (1936) alternative theory of aggregate economic activity levels in a capitalist economy, based upon his principle of effective demand, rather than the aggregate activity levels and the demand for factors of production adapting to the supply of factors of production (the potential productive capacity of the economy), activity levels and aggregate labor employment are regulated by aggregate effective demand for commodities, with persistent labor unemployment possible if not likely. It follows also from this that, *vis-à-vis* marginalism,

the equilibration of planned saving and investment is turned on its head, so to speak: rather than saving being the prerequisite for investment, investment determines saving via a 'multiplier' mechanism (Garegnani, 1978–79).

Entrepreneurship

In both the classical and marginalist traditions of economic theory, the fundamental object of analysis with respect to profits is the rate of return for the provision of capital in production, as such, notwithstanding very different theories of the profit (interest) rate in these two frameworks. What about the figure of the 'entrepreneur' in capitalism, and her remuneration? There is a loose sense of the term, commonly employed, in which the entrepreneur is merely the primary decision-maker in the firm or economic enterprise: the agent who organizes production and sale and so on. There is also the aspect of risk-bearing in production and sale. In the classical tradition, these two sorts of economic phenomena can be reduced to a species of labor and of capital provision respectively: managerial and organizational functions can be conceived of as a particular kind of labor earning wages, and the theory of profit rates on capital can conceptualize profits as proportional to both the quantity of capital invested and the degree of exposure to risk – risk of business failure or default in particular. (There is also a differential illiquidity aspect to different forms of capital, also generating profit rate differentials under competitive conditions.) The same kind of reduction can be accommodated within the marginalist framework.

But it is evident that in both the classical and marginalist traditions, a positive rate of profit (interest) is not primarily attributed to 'risk,' although risk and differential risk can be incorporated as additional factors in gross rates of return on capital in both approaches. In the former, net profits are fundamentally a realization of part of the distribution of the social surplus, depending in particular upon the forces regulating real wages; in the latter, net profits are a remuneration for 'waiting' – for abstention from consumption (saving). From the standpoint of both theories, an economy subject to complete certainty with respect to economic outcomes – e.g., a steady-state growing economy or a stationary economy, with all the economic agents' expectations of the future completely fulfilled – in general will exhibit a positive, equilibrium general rate of profit (interest).

But there is a stronger sense of entrepreneurship – which is not reducible to some combination of managerial labor and risk exposure – conceptualized in somewhat different ways in seminal contributions by Joseph Schumpeter (1883–1950; 1934[1911]) and Frank Knight (1885–1962; 1933[1921]). In the former, the focus is upon the entrepreneur as the economic agent driving innovation (e.g., technical progress); in the latter, it is exposure to 'uncertainty' of pecuniary outcome in *unprecedented* economic situations – conditions of uncertainty (rather than mere risk) in the radical sense that no well-defined probability distribution over all possible outcomes of the enterprise exists. This uncertainty cannot be reduced to calculable risk for which an ex ante required remuneration could be specified. It is economic action or decision-making in these kinds of conditions or situations, which constitutes the substantial sense of entrepreneurship.

What the contributions of Schumpeter and Knight point to is that the notion of a normal or equilibrium rate of remuneration for entrepreneurship, in that substantial sense of the term – remuneration that would be akin to normal or equilibrium rates of remuneration for labor or capital (under competitive conditions) – does not really make sense. Rather, the entrepreneur, properly understood in this substantial sense, is the 'residual claimant' to the net revenues of an innovative or unprecedented enterprise – the gross revenues net of the remuneration of all other contributors to the enterprise. And more often than not, the residual will be nonpositive; that is to say, the majority of 'entrepreneurs' (properly understood) actually fail. 'Profit,' in some indeterminate sense as to magnitude, might be a motivation (or even the sole motivation) to entrepreneurial activity; but there can be no definite rate of return to entrepreneurship, which can be conceived of as bringing forth an equilibrium supply of entrepreneurship. Entrepreneurship in this strong sense might better be thought of as akin to a scarce natural (human) resource, which may earn a kind of scarcity rent, even if such remuneration is commonly called profits.

Rates, Shares, and Levels

In the discussion of classical and marginalist economics above the focus was upon rates of profit (interest) on capital. What about the share of profits in revenue and the absolute level of profits – whether at the firm, industry, or economy-wide level? If we suppose we have a sound or plausible theory of the general rate of profit (interest) – whether the classical surplus approach, the marginalist approach, or some other – and of equilibrium profit rate differentials, are there equilibrium profit shares and equilibrium absolute levels of profits, associated with the equilibrium profit rates?

Conceptually at least, it is straightforward to derive shares and levels from rates. The share of profits in the gross or net revenue of a firm, an industry, or an economy will be equal to the relevant profit rate times the capital-output ratio of the firm, industry, or economy. (For the share in gross revenue, the 'output' measure will be gross revenue from sales; for the share in net revenue, the output measure will be value added.) Then one can arrive at the absolute level of profits as the relevant profit share times the level of output of the firm, industry, or economy. But are there equilibrium capital-output ratios and equilibrium output levels, analogous to equilibrium profit rates?

The answers are more clear-cut for the marginalist approach. The general equilibrium character of the theory, with all variables simultaneously determined, means that capital-output ratios are simultaneously determined with profit rates, as a consequence of the supposed existence of demand functions for capital, in which capital-output ratios are a negative function of the general rate of interest (profit). In the modern reconstruction of the classical approach, arising out of the seminal work of Piero Sraffa (1898–1983; 1960), it can also be shown that – given the level of real wages or the general rate of profit – the profit-maximizing

capital-output ratios are determinate (whether or not firms and industries have a spectrum of alternative production methods available to them). But there are no demand functions for factors of production, as in the marginalist framework, entailed by, or required for, those results in the modernized classical framework. Furthermore, it is not necessary that *every* firm or enterprise in an industry should exhibit the profit-maximizing capital-output ratio: only the 'dominant' production method employed in an industry will be associated with that capital-output ratio; and firms employing that dominant production method will only exhibit that equilibrium capital-output ratio, and associated equilibrium profit share, when the level of output produced enables 'normal' or desired rates of utilization of the firms' capital stocks.

With regard to absolute levels of profits, also in the marginalist framework economic activity levels are simultaneously determined with profit rates and capital-output ratios. Hence, absolute levels of profits are fully determined in the general equilibrium. These equilibrium activity levels are associated with full employment of factors of production due to the 'supply-side' determination of activity levels in that approach. In classical economics, the issue of absolute levels is more complicated since there is not really a theory of aggregate activity levels to be found there (although Marx has interesting insights on the subject). However, a Keynesian demand-side determination of activity levels and aggregate outputs can be synthesized with the classical approach to income distribution and prices (Garegnani, 1983). A classical-Keynesian synthesis along these lines enables a determination of equilibrium outputs and profits, radically different from the marginalist approach. But this proposition is subject to a caveat, derivative from the qualification above concerning dominant production methods: a demand-side, Keynesian determination of activity levels does not necessarily entail that all firms in the industries making up the economy exhibit equilibrium capital-output ratios, nor that firms are operating at normal or desired rates of utilization of capital.

Independently of Keynes, and at about the same time, Michal Kalecki (1899–1970) also formulated a demand-side approach to explaining economic activity levels – the principle of effective demand – along essentially the same lines as Keynes. From the point of view of the theory of profits, what is of particular interest about Kalecki's formulation of the theory is that the multiplier mechanism, whereby planned investment spending determines planned saving, is shown to be also a principle for determining the absolute level of aggregate profits in the economy as a whole (e.g., Kalecki, 1937). To see this logic, suppose a simple case in which the aggregate income of the economy is divided between wages and profits; 'households' earn the wages and spend them entirely on consumption; and 'firms' earn the profits and engage in spending on investment, the latter spending being determined independently of the level of profits. Aggregate revenue to the firms will be governed by the sum of consumption and investment spending; and their aggregate profits will be that spending net of aggregate wages paid. Hence, since aggregate wages equal consumption spending, aggregate profits are determined by the level of investment spending. The same essential logic continues to apply under more general assumptions (notably, saving by wage earners, consumption by profit recipients, the existence of a public sector, and foreign trade and financial flows).

Conclusion

In the view of the present writer, the modern reconstruction of the classical approach, combined with Keynes's approach to economic activity levels, provides a more robust and plausible framework for the theory of profits than the marginalist approach. As a matter of fact, subsequent to the faltering of the marginalist general equilibrium research program of the immediate decades after World War II, in marginalist economics there is not much interest any more in addressing the 'big question' of the determination of the general rate of return on capital as such (although the notion is more or less entailed, or at least implied, by conventional macroeconomic models). In mature liberal capitalism, with sophisticated financial systems (in particular, largely autonomous credit creation by banks), it is possible for theory in a classical-Keynesian framework to affirm that profit rates on capital in production and interest rates on financial instruments are brought into alignment by competition (not necessarily strict equality), but to turn the traditional causation (from profit rates to interest rates) on its head, so to speak. Instead of the general rate of profit being the independent variable determining the general level of interest rates, the latter – independently determined by monetary policy interacting with financial markets – regulates profit rates. Both Keynes (1936: pp. 202–204) and Sraffa (1960: p. 33), from rather different perspectives, pursued this fruitful idea. A confirmation of the validity of that conception of the determination of the profitability of capital would give transparency to the ultimately arbitrary or conventional character of the magnitude of pure profits (rates, shares, and absolute levels) – profits as the appropriation of a part of the social surplus, rather than a necessary supply price of capital in the manner of marginalism.

Program Evaluation

Christiane Spiel, Barbara Schober, and Evelyn Bergsmann, University of Vienna, Vienna, Austria

Abstract

Evaluation systematically investigates characteristics and merits of programs and can be done in all phases of a program. The purpose of evaluation is to provide information on the effectiveness of programs so as to optimize outcomes, quality, and efficiency. The article gives an introduction to program evaluation by considering the following four questions: What is program evaluation? At what levels can programs be evaluated? What standards can be set to enhance the quality and fairness of evaluation? How can benefits to users be achieved?

Evaluations are, in a broad sense, concerned with the effectiveness of programs. While common sense evaluation has a very long history, evaluation research, which relies on the scientific method, is a young discipline that has nevertheless grown massively in recent years. In the last few decades, program evaluation has made important contributions to various social domains, e.g., to education, health, economics, and environment. This article gives an introduction to program evaluation by considering the following four questions: What is program evaluation? At what levels can programs be evaluated? What standards can be set to enhance the quality and fairness of evaluation? How can benefits to users be achieved?

What Is Program Evaluation?

Definition, Distinction from Other Activities, Users and Doers of Evaluations

Evaluation, broadly construed, has a very long history. For example, in ancient Rome, tax policies were altered in response to observed fluctuations in revenues, and many thousands of years ago, hunters developed complicated procedures for fishing and trapping. In recent years, common sense program evaluation has evolved into evaluation research, which relies on scientific research methods. This article focuses on this last type of evaluation (for introductory texts on evaluation research see, e.g., Berk and Rossi, 1999; Fink, 2005; Mathison, 2005; Mertens and Wilson, 2012; Rossi et al., 2004; Stufflebeam and Shinkfield, 2007; Wholey et al., 2010).

In what follows, the terms evaluation, program evaluation, and evaluation research are used synonymously. Concern for the first large-scale national evaluations of social programs in the USA first arose as part of the War on Poverty, and methods for monitoring programs are still evolving rapidly. Evaluation has proven its usefulness to such an extent that most federal and state agencies require evaluations of new programs.

Programs are the objects of evaluation, sometimes also called projects or interventions. Program evaluation derives from the idea that social programs should have demonstrable merits and explicit aims by which success or failure may be empirically judged. For example, literacy programs for high school students should lead to measurable improvements in their reading skills. Introductory texts on evaluation describe programs as systematic activities that are provided on a continuing basis to achieve preplanned purposes e.g., a national program to train teachers to work in rural and underserved areas, a campaign to vaccinate all children in a school district (e.g., Fink, 2005; Joint Committee on Standards for Educational Evaluation, 2011).

Evaluation systematically investigates characteristics and merits of programs. It is the purpose of evaluation to provide information on the effectiveness of programs so as to optimize outcomes, quality, and efficiency. Program evaluations are conducted by applying many of the same methods that social researchers rely on to gather reliable and valid evidence. These include formulating the study questions, designing the evaluation, setting standards to assess the program impact, conducting ongoing monitoring of the program functioning, collecting and analyzing data, assessing program effectiveness relative to costs, and reporting results. For examples of evaluation in various fields of clinical and applied psychology see, e.g., Bickman et al. (1995), Gueron and Pauly (1991), Hope and Foster (1992), Maggin et al. (2011), Spiel et al. (2006), or Wong et al. (2008).

While a few authors (e.g., Scriven, 2002) take the view that theories are a luxury for the evaluator and not essential to explanations, the majority of researchers call for injections of theory into every aspect of evaluation design and analysis (e.g., Berk and Rossi, 1999; Coryn et al., 2011; Jacobs et al., 2012; Mathison, 2005). This implies that program evaluation capitalizes on existing theory and empirical generalizations from the social sciences, and is, therefore, after all, applied research.

By relying on the scientific method, program evaluation differs from activities such as newspaper reporting and social commentary. Program evaluation differs from the social sciences in its goals and audience. Evaluation goals are defined by the client, that is, the individual, group, or organization that commissions the evaluator(s), e.g., policy makers. However, often programs and clients do not have clear and consistent goals that can be evaluated for effectiveness. Therefore, to meet evaluation standards, program evaluation should be conducted by professional evaluators who are experts in the social sciences, using a broad repertoire of concepts and methods, but who also have expertise in project and staff management and have at least basic knowledge of the evaluated domain.

While the impetus for evaluation rests in policy, information from evaluations are used by the *stakeholders*, all individuals, or groups that may be involved in or affected by a program evaluation. These are at least six groups (Fink, 2005): (1) federal, state, and local government, e.g., a city,

the National Institute of Health; (2) program developers, e.g., health care service providers, the curriculum department in a school; (3) communities, e.g., a geographically contiguous area, people with a shared health-related problem; (4) policy maker, e.g., a state subcommittee on human services; (5) program funders, e.g., the Department of Education; (6) social researchers, e.g., in government, public agencies, and universities. Therefore, program evaluation is also an interdisciplinary task where evaluators and stakeholders work together (Cousins and Chouinard, 2012).

Key Concepts and Assignment Criteria

Evaluation can and should be done in all phases of a program. *Baseline data* collected before the start of the program are used to describe the current situation, e.g., the need for an intervention. In addition, baseline data are used to monitor and explain changes. For example, if the emergency medical services attempt to reorganize their service to better care for children, they may collect interim data to answer questions such as: In what cases did the emergency medical services fail to meet the needs of critically ill children? What are the differences between their needs and the needs of adults? What is the current performance of medical staff?

Before the start of the program a *prospective evaluation* can be employed to determine the program's potential for realization, its effectiveness, and its impact, that is, the scope of its effects.

In *formative evaluation*, interim data are collected after the start of a program but before its conclusion. The purpose of formative evaluation is to describe the progress of the program and, if necessary, to modify and optimize the program design.

A *process evaluation* is concerned with the extent to which planned activities are executed and therefore is nearly always useful. For example, process evaluation can accompany implementation of a community-oriented curriculum in medical schools.

Outcome evaluation deals with the question of whether programs achieve their goals. However, as mentioned before, goals are often stated vaguely and broadly and therefore *program effectiveness* is difficult to evaluate. In practice, the concept of effectiveness must always address the issue 'compared to what?' Often, it is difficult to distinguish program effects from chance variation and from other forces affecting the outcome. Berk and Rossi (1999) distinguish between marginal effectiveness, relative effectiveness, and cost-effectiveness. *Marginal effectiveness* concerns the dosage of an intervention measure. For example, to prove the assumption that a better student–teacher ratio would improve student performance, the classroom size has to be reduced. In this case, two or more different student–teacher ratios are the doses of intervention and their outcomes are compared.

Relative effectiveness is evaluated by contrasting two and more programs, or a program and the absence of the program. For example, lecture-based learning can be contrasted with problem-based learning in its effects on students' practical performance.

Cost-effectiveness considers effectiveness in monetary units. Evaluation is usually concerned with the costs of programs and their relationship to effects and benefits. For example, in the evaluation of a physical education program, one can ask how much gain in monetary units can be expected due to reduced use of health services.

The entire impact of a program e.g., the extent of its influence in other settings is very difficult, maybe even impossible, to assess. Here, *impact evaluations* are applied, that is, historical reviews of programs are performed after the programs have been in operation for some period of time. If a new medical education program was implemented, an improvement in the quality of the entire health system might be expected as an impact of the program. However, the evaluation of such an improvement might be extremely difficult.

At What Levels Can Programs Be Evaluated?

Programs can be evaluated not only in different phases but also on different levels. Kirkpatrick (1998; Kirkpatrick and Kirkpatrick, 2010; see also Spiel, et al., 2010a) defined four sequential levels; each level is important and has an impact on subsequent levels. The evaluation process becomes more difficult and time-consuming at higher evaluation levels, but it also provides more valuable information. In the following paragraphs, the four levels are briefly described using a parenting program as an example (see Spiel and Strohmeier, 2012).

Level 1 – Reactions

Evaluation on this level measures how program participants react to the program. Therefore, on this level customer satisfaction is measured. For instance, when parents are asked how much they have liked attending a course on parenting styles, this kind of evaluation would tap the level of reactions.

Level 2 – Learning

Learning can be defined as the extent to which participants change attitudes, improve knowledge, and/or increase skills and competencies as a result of attending the program. That means, for example, that this kind of evaluation would investigate whether parents have improved their competencies after attending a course on parenting styles. Such an evaluation could apply questionnaires or tests before and after the course.

Level 3 – Behavior

Evaluation on this level investigates whether changes in behavior have occurred because of attending a program. Thus, the question of whether the learning can be transferred into everyday life is crucial for this kind of evaluation. When using the example of the parents attending a course on parenting styles, the question of whether they would apply what they have learned to their daily parenting behavior is the main goal of an evaluation study focusing on this level. Observations or interviews with the children might be the methods of choice in that specific case.

Level 4 – Results

Here, the focus of the evaluation is on the final results occurring because of participation in the program. The final results can

include, for instance, increased production, improved quality, increased sales, decreased costs, or higher profit. Taking the parenting styles course as an example, an evaluation on this level would measure the adaptation outcomes of the children of participating parents in the long run. However, population and sample selection have to be carefully defined for such an evaluation.

What Standards Can Be Set to Enhance the Quality and Fairness of Evaluation?

Because of the increasing number of evaluations and the high impact that decisions based on results of evaluations may have, there has been an ongoing discussion since the early 1970s about guidelines for effective evaluations. In the absence of any clear definition of what constitutes a reasonable program evaluation, the *Joint Committee on Standards for Evaluation Research* (JCSEE) in cooperation with evaluation and research specialists compiled knowledge about program evaluation and established a systematic process for developing, testing, and publishing evaluation standards. The Joint Committee began its work in 1975. In 1989, the progress for developing standards was adopted by the American National Standards Institute, and became available worldwide.

Originally, the standards were developed to guide the design, implementation, and assessment of evaluations of educational programs, projects, and materials. Since then, the *Program Evaluation Standards* (JCSEE, 2011) have expanded to include applications of the standards in such other settings as medicine, nursing, the military, business, law, government, and social service agencies. The standards are published for people who commission and conduct evaluations as well as for people who use the results of evaluations.

The Joint Committee defined an *evaluation standard* as a principle that is mutually agreed upon by people engaged in the professional practice of evaluation, that, if met, will enhance the quality and fairness of an evaluation (JCSEE, 2011). The standards provide advice on how to judge the adequacy of evaluation activities, but they do not present specific criteria for such judgments. The reason is that there is no such thing as a routine evaluation, and the standards encourage the use of a variety of evaluation methods. The 30 standards are organized around the five important attributes of sound and fair program evaluation: *utility*, *feasibility*, *propriety*, *accuracy*, *and evaluation accountability* (JCSEE, 2011).

Utility standards guide evaluations so that they will be informative, timely, and influential. They require evaluators to keep the stakeholders' needs in mind in all phases of the evaluation. The eight standards included in this category are Evaluator Credibility, Attention to Stakeholders, Negotiated Purposes, Explicit Values, Relevant Information, Meaningful Processes and Products, Timely and Appropriate Communication and Reporting, Concern for Consequences, and Influence.

Feasibility Standards call for evaluations to be realistic, prudent, diplomatic, and economical. They recognize that evaluations usually are conducted in natural settings. The four standards included in this category are Project Management, Practical Procedures, Contextual Viability, and Resource Use.

Propriety Standards are intended to facilitate protection of the rights of individuals affected by an evaluation. They urge evaluators to act lawfully, scrupulously, and ethically. In this category, seven standards are included: Responsive and Inclusive Orientation, Formal Agreements, Human Rights and Respect, Clarity and Fairness, Transparency and Disclosure, Conflicts of Interests, and Fiscal Responsibility.

Accuracy Standards are intended to ensure that an evaluation will reveal and transmit accurate information about the program's merits. They determine whether an evaluation has produced sound information. The eight accuracy standards include Justified Conclusions and Decisions, Valid Information, Reliable Information, Explicit Program and Context Descriptions, Information Management, Sound Designs and Analyses, Explicit Evaluation Reasoning, and Communication and Reporting. *Validity* refers to the degree to which a piece of information or measure assesses what it claims to assess, while *reliability* refers to the degree to which a piece of information is free from 'measurement error,' that is, the exactness of the information.

Evaluation Accountability Standards propose the need to investigate, document, and improve evaluation quality and accountability. The three standards included in this category are Evaluation Documentation, Internal Metaevaluation, and External Metaevaluation. *Metaevaluation* is the evaluation of an evaluation. Internal Metaevaluations are done by the commissioners of the evaluation, whereas External Metaevaluations are conducted by evaluators who are not involved in the evaluation at hand.

For each standard, the Joint Committee has summarized guidelines for application and common errors. In addition, one or more illustrations of the standard's application are given (JCSEE, 2011). However, the Joint Committee acknowledges that the standards are not all equally applicable in every evaluation. Professional evaluators must make a selection, identifying those that are most applicable in a particular context. Evaluation standards are also provided by other committees and associations, such as Guiding Principles for Evaluators (American Evaluation Association, 2004; for further information on different standards see Patton, 2012).

How Can Benefits to Users Be Achieved?

Types of Evaluation Utilization

The utility standards present different approaches to enhance the utility of an evaluation. But there is not just one point of view concerning evaluation utilization; different types of evaluation utilization have emerged in recent decades (Contandriopoulos and Brousselle, 2012; Fleischer and Christie, 2009). Rossi et al. (2004) mentioned three types of utilization of evaluations: instrumental, conceptual, and persuasive/symbolic (see also Balthasar, 2006; Johnson, 1998). Balthasar and Johnson added process use/process-related use, a type that was originally suggested by Patton (1997; see also Alkin, 2005; Weiss et al., 2005). Weiss et al. (2005) added the so-called imposed use to the four aforementioned types. As a matter of course, imposed use is not yet an established type of use. **Table 1** presents descriptions of these five types of evaluation utilization (see also Bergsmann and Spiel, 2009).

Table 1 Types of evaluation utilization

Types of evaluation utilization	*Explanation*
Instrumental use	Indicates "instances where respondents in the study could document the specific way in which the social science knowledge had been used for decision-making or problem-solving purpose" (Alkin, 2005: p. 435).
Conceptual use	Indicates "instances in which the knowledge about an issue influences a policy maker's thinking although the information was not put to a specific, documentable use" (Alkin, 2005: p. 435).
Symbolic use	Indicates instances in which evaluations are used to "justify preexisting preferences and actions" (Weiss et al., 2005: p. 13).
Process use	"The evaluation process itself could have impact; that is, it could lead to utilization … the act of conducting an evaluation and the interactions between the evaluator and various stakeholders can lead to changes in the individuals or in the organisation. Thus it is not the findings of the evaluation that contribute to use but the process itself" (Alkin, 2005: p. 435).
Imposed use	"It is a type of use that comes about because of pressure from outside" (Weiss et al., 2005: p. 16).

User-Oriented Evaluations

The future of evaluation is tied to the future effectiveness of programs (Patton, 1997). However, in order to improve programs, users' perspectives have to be integrated into program evaluation. Moreover, according to Patton (2012), the specific use of an evaluation should be defined by the users. Consequently, user-oriented evaluation is recommended because it requires and promotes systematic and continual critical reflection and feedback. Participants have the opportunity to learn the logic of evaluation and the discipline of evaluation reasoning. Prominent evaluation concepts in this field are utilization-focused (Patton, 1997), empowerment (Fetterman and Wandersman, 2005), participatory (King and Cousins, 2007), and collaborative evaluations (Cousins and Shulha, 2008).

Patton (1997; see also 2012) proposed the concept of utilization-focused evaluation. According to him, the evaluator and the users work together to reach the utilization defined by the users. Patton (2012) divides the evaluation into several steps (see **Figure 1**); each step should contribute to the specific and intended use.

The first step is to start with stakeholder analysis: After identifying potential intended users of the evaluation, the primary intended users should be determined. They are then invited to clarify and prioritize the primary purposes and intended uses of the evaluation. Determining purposes and intended uses of the evaluation is a further crucial step in the utilization-focused evaluation process. This step, including the prioritization of the evaluation questions, is expatiated in

Figure 1 Concept of utilization-focused evaluation.

detail in the following section. The following steps of the utilization-focused evaluation process (Figure 1) are similar to scientific research. However, users should be actively involved in all steps. The final step of the process is a metaevaluation of the evaluation (see also JCSEE, 2011).

Empowerment evaluation is another model that aims at improving the evaluated program, mostly through the development of the skills and autonomy of selected participants (Fetterman, 2005; Fetterman and Wandersman, 2005). It is generally conducted with a pool of program staff members and stakeholders who will be actively involved in identifying evaluation questions, collecting and analyzing data, and formulating next steps.

Goal Explication as an Important Prerequisite for User Orientation

Evaluation goals, including the intended uses, are defined by the clients who commission the evaluation. However, clients often do not have clear and consistent goals – either for their programs or for the evaluation – that can be evaluated for effectiveness. Consequently, they have not developed a kind of working model that relates actions within the program to the program goals. In such cases, professional evaluators should systematically work with the clients and representatives of all stakeholder groups to answer the following central questions (Spiel et al., 2010a; see also Spiel et al., 2012): (1) What are the goals of the program? (2) How should these goals be achieved? (3) How could program effectiveness (goal attainment) be recognized? (4) Are the needed resources available?

A workshop on goal explication is commonly organized to answer these four questions (see Spiel et al., 2010b). Using a wide range of facilitation techniques, the clients and stakeholders are supported in precisely describing their evaluation goals and prioritizing them (Question 1). Very often, the congruence between goals and activities is rather weak. Evaluators help the clients identify how the intended activities might work and how they can contribute to reaching the intended goals (Question 2). This also includes the systematic discussion of whether the resources needed (money and staff, but also the stakeholders' willingness to participate in the program) are available (Question 4). Answering the third question is typically very difficult for the clients of evaluation. They have to identify measureable indicators of effectiveness, labeled 'operationalization' in scientific research (Vogt and Johnson, 2011). Consequently, answering the third question also includes defining the goals of the evaluation. Again, evaluators use facilitation techniques to support the process of identifying the indicators for effectiveness. If possible, criteria for effectiveness are also defined (Fink, 2005). Applying such a procedure should also contribute to establishing an 'evaluative attitude' in the clients and stakeholders in the long run.

Concluding Remarks

In the last few decades, the demands for sound program evaluation have continued to grow in such a way that some authors (e.g., Pawson and Tilley even in 1997) fear it may become mandatory that everything be evaluated. Therefore, it is essential that quality control procedures and standards are introduced for all facets and tasks of evaluation and that the evaluation itself is evaluated against pertinent standards. Furthermore, the user orientation should be systematically considered. Several authors have made recommendations on how to recognize and consider the users' needs. However, there is also the risk of oversimplifying and only using a checklist of standards. But there is no fixed recipe of how to run a successful evaluation.
